ENGINEERING:

An Illustrated Weekly Journal.

EDITED BY W. H. MAW AND B. ALFRED RAWORTH.

VOL. XCVIII.—FROM JULY TO DECEMBER, 1914.

London:

OFFICES FOR ADVERTISEMENTS AND PUBLICATION—35 & 36, BEDFORD STREET, STRAND, W.C.

1914.

INDICES.

	Pages.
General	iii. to xvii.
One-Page and Two-Page Plates	xviii.
Literature	xix.
Letters to the Editor	xx.
Paragraphs	xxi. to xxiii.
Patent Record	xxiv. and xxv.
Classified Directory of Current Advertisements in "ENGINEERING"	xxvi. to xxxiv.
Addresses (and Telegraphic Addresses, if any) of Firms Advertising in "ENGINEERING"	xxxv. to xl.
Key to Telegraphic Addresses of Advertisers	xli. to xlvi.

GENERAL INDEX.

(*Illustrated Subjects are Marked with an Asterisk after the Number of the Page.*)

A.

ABERDEEN, Investigations of Upper Atmosphere at, 728
Absorption and Adsorption, Phenomena of, 579
— of Gases by Finely-Divided Copper, 679
— Pyrometer for Case-Hardening, 134*
Abutments, Bridge, Setting out, 117*
Acceleration of Steam and Electric Trains, 318*
Accessories, Motor-Car, S. Smith and Son's Works, 562*

Accidents:

Boiler Explosions Act, Working of, 476
Collisions through Suction between Passing Ships, 195*, 228*, 243*
Explosion, Dynamite, Panama Canal Construction, 256
— in Electric Mains, 58
— of Heating Boiler at Southsea, 472
— of Oil-Separator, Staveley Coal and Iron Co., 171
Railway Accidents, British, 365
Ships Lost, Lloyd's Statistics, 161, 301, 644
Steam-Pipe Explosion at Armstrong, Whitworth and Co.'s Works, 441
See also PARAGRAPH INDEX

Accumulators, Electric. See *Electric*
Acetylene-Oxygen Blow-Pipe. See *Blow-Pipe*
Acfield, W. C., on Audible Signalling on Railway Trains in Motion, 747, 765
Acid, Nitric, in Rainfall near Melbourne, 692
— Plants, Pollution of Air by, 281
Acoustics, Text-Book on (Review), 173
Adams, W. E., on Australian Ports, 356
Address, Presidential. See *Presidential Address*
"Admiral von Tirpitz," S.S., Trials of Föttinger Transformer for, 399
Admiralty Brass Condenser-Tubes, Effect of Coke on Corrosion, 342*, 489
— Courts, U.S., Cases of Collisions Due to Suction, 243*. See 195*, 228*
— See also *Warships*
Adsorption and Absorption, Phenomena of, 579
Advisory Committee on Aeronautics, Work of, 481, 763
— Committee, Sheffield University, 587
Aerial Navigation. See *Aeronautics*
— Ropeway. See *Wire Ropeway*
Aerials, Radiotelegraphic, Capacity of, 553
Aerodynamics. See *Aeronautics*

Aeronautics:

Advisory Committee on Aeronautics, Work of, 481, 763
Aerodynamics, Relation between Heat Transfer and Skin Friction, 481
— Wind Pressures near Cylindrical Rods, 257*. See LETTER, 301*
Aeronautical Construction, Suggested Board of, 764
Aeroplanes and Airships, Comparisons between, 313*, 338
— and Airships in Warfare, 312*, 338, 367, 392, 422*, 452*, 481, 513, 539*, 568, 596*, 626, 650, 680, 710, 762
— Attacking Submarines, 597*
— Bomb-Dropping, 568, 597*
— British, Superiority, 762
— Defence Against Gun-Fire, 368, 392, 513
— Design, Principles of, 543
— Design, Work of Royal Aircraft Factory, 763, 764
— Discharging Rockets and Torpedoes, 568, 597
— Dropping Steel Darts, 568
— Government *versus* Private Manufacture, 763
— Hostile, Liability for Damage by, 511
— Light Projectiles for Firing from, 540
— Military Value of Speed in, 765
— Naval, Floating Base for, 626
— Requirements of Machine-Guns for, 482, 513
— Struts, Design of, 403*
— Use of Explosive and Expanding Rifle Bullets against, 539*
— Use of Guns against, 367, 392
— Use of Lewis Machine-Gun on, 392, 482, 513
— Use in Naval Warfare, 596*, 626, 681
— Use of One-Pounder Guns on, 482, 513. See 540
— in Warfare, International Regulations, 710

Aeronautics—*continued.*

Air Currents, Pressures near Cylindrical Rods in, 257*. See LETTER, 301*
— Power and Sea Power, Relative Importance of, 710
— Resistance and Heat Transfer, Relation between, 481
Aircraft, All the World's (Review), 311
— Factory, Royal, Work of, 763, 764
Airships and Aeroplanes in Warfare, 312*, 338, 367, 392, 422*, 452*, 481, 513, 539*, 568, 596*, 626, 650, 680, 710, 762
— Discharge of Torpedoes from, 597*
— Hostile, Liability for Damage by, 511
— in Warfare, International Regulations, 710
— Zeppelin, Comparisons with Aeroplanes, 313*, 338
— Zeppelin, Methods of Attack, 338, 513, 568
— Zeppelin in Naval Warfare, 596*, 626, 681
Aviation Research, 543
Balloons, Investigation of Upper Atmosphere by, 654, 728
Barographs, Tests of, at National Physical Laboratory, 76
Board of Aeronautical Construction, Suggested, 764
Engine, Petrol, Aeroplane, Fullagar Balanced, 105*. See 74, 77, 100*, 164
— Petrol, Aeroplane, "Gnome," Work Absorbed in Cooling, 481
— Petrol, Aeroplane, War-Office Trials, 507
Flight without Formulæ (Review), 272
— Principles of (Review), 163
Hydro-Aeroplanes, Attacking Submarines by, 597*
— Bomb-Dropping, 597*
— Floating Base for, 626
— Floats, Design of, 29*, 166*
— Flying-Boat and Double-Float Types, 626
— Use in Naval Warfare, 596*, 626, 681
Royal Aircraft Factory, Work of, 763, 764
War Office Trials, Aeroplane Engines, 507
Wind Pressures near Cylindrical Rods, 257*. See LETTER, 301
Zeppelin Airships. See *Airships*
See also PARAGRAPH INDEX

Afforestation in Great Britain, 280
"Agincourt," H.M.S., Steam Trials of ("Sultan Osman I."), 155. See 189, 201
Agreements, Labour. See *Labour*
Agricultural Hall. See *Exhibition*
— Machinery, British and German Trade Competition, 282, 510
— Machinery, Smithfield Show of, 707*
— Motors. See *Engines; Motors; Tractors*
— Oil and Petrol Engines for Foreign and Colonial Markets, 281
— Research, State or University Control of, 692
— Society, Royal, Shrewsbury Show, 18*, 37*. See 80*, 98*
— Society, Royal, Trials of Motor Ploughs and Tractors, 40
— Tractors. See *Tractors*
Agriculture and the Electrification of the Atmosphere, 553
— Fertility of Lower Egypt, 552
— Growth of Cotton in Egypt, 552
— in Italy, Effect of Irrigation, 371*
— in New South Wales, Statistics of, 276
— Preparation of Land for Irrigation, 374*
— See also *Irrigation* and PARAGRAPH INDEX
Air, Compressed. See *Compressed Air; Pneumatic*
— Compressors, Heenan and Froude's Water-Coolers for, 313*. See LETTER, 531
— Compressors for Schneider Diesel Engines, 100*. See 74
— Compressors, Six-Stage, Odda Cyanamide Works, 408*
— Compressor, Three-Stage, for Diesel Engine (Brotherhood), 165*
— Coolers for Electric Generators, Revolving-Cylinder Type, 314*. See LETTER, 531
— Currents, Pressures near Cylindrical Rods in, 257*. See LETTER, 301*
— Distribution of Moisture in England and Wales, 728
— Effect in Surface-Condensers, 635*, 647, 648, 656. See *Erratum*, 670
— Effect of, on Wireless Signals, 106, 580
— Electrification of, 106, 553
— Filters, Water-Spray Type, 502*. See LETTER, 531. See *Addendum*, 590
— Hoists for Foundry Work, 721, 722*
— Injection Pressures, Diesel Engines, 78, 263*
— Ionisation of, Effect on Ventilation, 687
— Linde Plant for Producing Nitrogen from, 406*
— Pollution of, by Chemical Works, 280
— Pressure on Gas-Holders, 301*. See 257*
— Pump. See *Pump*
— Purification Plant for Tube Railway, 502*. See LETTER, 531. See *Addendum*, 590
— Relief-Valve, Locomotive Cylinders, 45*
— Resistance and Heat Transfer, 481
— in Rooms, Effect of Gas Lighting on, 131
— Supplied to Locomotive Boilers, Method of Calculating, 439
— Temperatures, Method of Measuring, 75
— in Tunnels, Tests with Steam and Electric Traction, 733
— Upper, Investigations of, 654, 728
— Valve, Reversing, for Open-Hearth Furnace, 242*
Aircraft and Airships. See *Aeronautics*
Albion, Mich., Ferro-Concrete Reservoir, 754*
Alby Carbide Factories. See *Odda*
Alcohol and Alcohol Mixtures, Trials of Motor-Car Engine with, 706
Alexandra Dock, Newport, 33*, 111*, 177*, 217*
Alkali Works, British, Report on, 280
Allen, K., on Sewage Clarification by Fine Screens, 652
Allen, W. H., Son and Co., Ltd.; Pumping Plant for Hull Docks, 6*
Allerdale Colliery, Kopper's Coke-Ovens at, 457*
Allmanna Svenska Electric Co.: Transformers and Regulating Apparatus, 353*
Alloys. See *Metallurgy, Micro-Photographs*, and PARAGRAPH INDEX
Alpha Particles, Scattering by Magnetons, 581
Alternating Current. See *Electric*
— Stress. See *Tests* (*Materials*)
Alternators. See *Generators, Electric*
"Altior" Process of Die-Casting, 131
Altoona Testing Plant: Influence on Locomotive Design, 17, 363, 393; Tests of Superheater Locomotives at, 18, 393
Aluminium, Action of Water on, 512
— Alloys. See *Alloys* under *Metallurgy*
— and Aluminium Alloys, Applications of, 595
— German and Austrian Trade in, 534
Ambidexterity and Mental Culture (Review), 405
America, Central and South, Social and Economic Conditions, 132
— Electric Vehicle Association of, Annual Convention, 188
— See also *United States*
American Admiralty Courts, Cases of Collisions Due to Suction, 243*. See 195*, 228*
— and British Competition, Iron and Steel Trade, 364
— Experiments on Fuel Briquetting, 126
— Institute of Mining Engineers. See *Mining*
— Society of Civil Engineers. See *Civil Engineers*
— Society of Naval Engineers; Lieut. S. M. Robinson on the U.S. Collier "Jupiter," 503*. See 619
— Society for Testing Materials, Report on Permeability Test for Paints, 159
— Trade Depression, 736
Amme, Giesecke and Konegen, A.-G., Swinging-Trough Conveyors, 465*
Ammonia Compressors, Refrigerating Plant, Odda Cyanamide Works, 408*
— Entropy-Heat Diagram for, 518*, 548*
Ammonium Sulphate, Manufacture of, 281
— Sulphate, Recovery from Coke-Oven Gas, 460*
Amorphous Cement Theory, Crystalline Structure of Metals, 357, 649, 657*
Anchorages, Manhattan Suspension Bridge, 379*
Anchors, German and Austrian Trade in, 331
Anjou, Iron Ore Deposits in, 421
Annealing. See *Heat Treatment* under *Metallurgy*
Annual Publications. See LITERATURE INDEX
Antarctic Meteorology, B.A. Discussion on, 654
Antennæ, Radiotelegraphic, Capacity of, 553
Antimony Prices. See *Metal-Price Diagrams*
Appointments. See PARAGRAPH INDEX
Apulia, Italy, Water Supply of, 336. See 374
Arc. See *Electric* and *Furnace*
Arch Bridges, Ferro-Concrete, at Lucknow, 122*; at Longtown, Cumberland, 341*
— Bridges, Long Span, Design of, 350
— Bridge, Old Cast Iron, at Longtown, Cumberland, 341*
Architects, Naval. See *Naval Architects*
Argentine, Buenos Aires, Ferro-Concrete Subways for, 409*
— Navigation Co., Ltd., Geared-Turbine Steamers for, 745*. See 726*
Armament. See *Guns; Warships*
Armature Binding Wires, Stresses in, 719*
Armour for Aeroplanes, 368, 392, 513
— under Water, for Battleships, 59, 65*. See 80
— See also *Warships* and *Naval* in PARAGRAPH INDEX
Armoured Ships. See *Warships*
Armstrong College, Newcastle-on-Tyne, Engineering Departments, 10*
Armstrong, Prof. H. E., on Education, 307
Armstrong, Whitworth and Co., Ltd.: New Shipyard at Walker-on-Tyne, 1*; see 62, 200; Hydraulic Tipping-Hoist for Coal-Wagons, Hull Docks, 8*; Warships Designed and Built at Elswick, 62, 200; see 155, 189; Sluice-Gates for Alexandra Dock, 116*; Reorganisation of Turkish Naval Construction Works, 127; Oil-Carrying Steamer "San Isidoro," 181*; Steam-Pipe Explosion at Openshaw Works, 441
Army Aeroplanes and Airships. See *Aeronautics*
— British, Engineering Societies' Battalion, 360, 386. See 393, 416, 498, 634
— Requirements, Manufacture of, and Recruiting, 335. See LETTER, 425
— Rifles, Development of, 450
Arnold and Large, Ltd.; Gas-Heated Drying-Barrel, 440*
Arrol, Sir William and Co., Ltd.; Lock-Gates for Alexandra Dock, 111*
Arsenical Copper, Properties of, at High Temperatures, 353*
Artesian Wells. See *Wells*
Articulated Locomotives. See *Locomotives*
Artillery. See *Guns* and PARAGRAPH INDEX
Arts, German Achievements in, 479. See LETTERS, 531, 587
— Royal Society of: Dr. W. R. Ormandy, on the British and German Chemical Industries, 676; Sir W. Tilden, on the Supply of Chemicals to Britain and her Dependencies, 677
Asquith, W., Ltd.: Portable Drilling and Boring-Machine, 441*; Horizontal Drilling, Tapping, and Boring-Machine, 726*
Association, British Engineers', and Trading with the Enemy, 413
— British. See *British Association*
— Engineering. See *Institutions*
— of Engineers-in-Charge; F. Broadbent on Electricity in the Printing Office, 740*
Astronomical Papers at British Association, 652
Atchison, Topeka, and Santa Fe Railroad, Mallet Locomotives on, 55*; 2-10-2 Type Freight Locomotive for, 558*
Atlantic Liners. See *Steamers*
"Atlantic" Locomotives on French Railways, 45*. See 40
Atmosphere, Electrification of, 106, 553
— Distribution of Humidity in, 728
— Effect of Gas-Lighting on, 131
— Effect on Wireless Signals, 106, 580
— Ionisation of, Effect on Ventilation, 687
— Pollution by Chemical Works, 280
— Temperature of, Method of Measuring, 75
— in Tunnels, Tests with Steam and Electric Traction, 733
— Upper, Investigations of, 654, 728
Atmospheric Air, Linde Plant for Production of Nitrogen from, 406*
— Electricity, Observations at Kew, 106
Atomic Weights, Report of Committee on, 567
— Weight of Copper, Determination by Electrolysis, 32
Atomisers, Oil-Fuel. See *Oil Fuel*
Atoms and Molecules, Structure of, 607, 666, 667
Auld, Alexander, The late, 563
Australia, Discovery and History of, 226. See 692
— Experiments on Wireless Signals in, 580
— Irrigation in, 552. See 691
— Melbourne, Nitric Acid in Rainfall, 692
— Mount Stromlo Observatory in, 653
— New South Wales, Statistics of Agriculture and Gold Production, 276
— Proposed Bridge over Sydney Harbour, 544
— Proposed Underground Railway, Sydney, 543
— Report on Solar Observatory, 652
— Trade Conditions and Requirements, 425

Australia (*continued*), Water Supply from Artesian Wells in, 553. See 691
— Wireless Telegraphy in, Balsillie System, 580
Australian Capital at Canberra, Proposed, 551
— Longitudes, B.A. Discussion on, 653
— Meeting of British Association. See *British Association*
— Ores, Extraction of Radium from, 691
— Ports and Modern Ships, 356
— Railways, Gauge Problem on, 566. See 692
— Railways, New South Wales, 451
— Railways, Bridge over Maribyrnong River, 680
Austria-Hungary, Naval Expenditure of, 384*
— Patentees and British Patents during War, 280, 309, 390. See LETTERS, 327, 360. See also 413, 454, 587
— State Railways, Analysis of Locomotive Tests, 438*, 468*
— Trade Statistics. See *Trade*
Austrian and British Trade Competition. See *Trade*
Autogeneous Welding. See *Welds* and *Welding*
Autographic Recorder, Photographic, Stress-Strain Diagrams Taken with, 287*
Automatic Centre Punch Hardness Tests, 138*
— Guns. See *Guns*
— Machine-Tools. See *Machine-Tools*
— Machinery and Labour Shortage in Cotton Industry, 159
— Sprinklers, Use on Ships, 57
Automobile Engineers, Institution of: L. H. Pomeroy, on the Effect of War on Motor-Car Industry, 480; see 423; L. H. Pomeroy, on the Shortage of Motor-Car Parts due to the War, 681, 728; Prof. W. Watson, Comparisons of Petrol and Petrol Substitutes, 706
— See *Motor Cars*
"Autopetrol" Petrol Storage and Delivery Apparatus, 475*
Auxiliary Machinery, Marine. See *Marine*
Avery's Weighing-Machine for Liquids, 40
Aviation. See *Aeronautics*
Axle-Boxes for Locomotive Trailing Truck, 740*

B.

BABCOCK and Wilcox, Ltd.; Overhead Crane for Foundry Work, 665*
Bacteriological Purification of Water, 449
— Treatment of Sewage, Imhof System, 567
Badana Dam, Italian Irrigation Works, 372*
Bags, Grain, Shoots for Glasgow Granary, 698*
Bairstow, L., on Critical Loads for Long Struts, 403*
Baker-street and Waterloo Railway, Air-Purification Plant for, 502*. See LETTER, 531. See *Addendum*, 590
Balance, Current, National Physical Laboratory, Measurements with, 30
— Induction, Location of Bullets by, 736*
Balanced Internal-Combustion Engine, The Fullagar, 74, 77, 100*, 104*. See 164
Balancing Internal-Combustion Engines, 74, 103.* See 77, 164
Balcke and Co.; Air-Filters for Turbo-Generators, 502*. See LETTER, 531. *Addendum*, 590
Baldwin Locomotive Works: 2-10-2-Type Locomotives for Freight Service, 556*; 2-8-8-8-2-Type Articulated Locomotive for Erie Railroad, 601*, 628*, 682*, 738*
Balfour, David, The late, 753
Ball, J. B., on Ferro-Concrete Structures on the Great Central Railway, 716
Ball-and-Socket Joint, Steam-Pipe for Locomotive, 740*
— Bearings. See *Bearings*
Ballistics, Energy Account in Gun-Fire, 539
— of French and German Field-Guns, 452
Balloons. See *Aeronautics*
Balsillie System of Wireless Telegraphy, 580
Baltic-Black Sea Canal Scheme, 254
Baltic Locomotives, French Railways, 48*. See 41
Baltimore and Ohio Railway: Mallet Locomotives on, 54*; 2-10-2-Type Freight Locomotive for, 558*
Band-Conveyors for Grain, Glasgow Granary, 634*, 693*
— Type Surface-Grinding Machine, 667*. See *Addendum*, 715
Banks, Financial Assistance to Manufacturers and Traders by, 254, 333, 419, 675. See LETTERS, 712, 725, 752
Barker, A. H., on Ventilation, 684
Barometers and Barographs, Tests of, 76
Barrel, Drying, Walker Gas-Heated, 440*
Barrow Association of Engineers; C. C. Humphris on the Military Small Arm, 450
— Vickers' Shipyard, Crane Equipment of, 69*
Bascule Bridges. See *Bridges*
Base, Floating, for Naval Aeroplanes, 626
— Lines, Measurement of, 117*
Bateson, Prof. W., on Heredity, 284, 515
Battalion, Engineering Societies', 360, 386. See 393, 416, 498, 634
Battered Walls, Setting Out, 175*
Batteries. See *Electric*
Battleships. See *Warships*
Bauche-Ivel Motor-Hoes, 19*
Bayliss, Thomas Richard, The late, 154
Beach Erosion and Protection. See *Coast*
Beams, Curved, Bending Stresses in, 321*, 377*
— Ferro-Concrete, Bending Stresses in, 347*
— Ferro-Concrete, Glasgow Granary, 584*
— Ferro-Concrete, Ratio of Elastic Moduli of Steel and Concrete, 347
— Rolling Load on, Dynamic Increment of, 327
Bearings, Ball, on Agricultural Machinery, 40
— Crank-Shaft, Motor-Car Engines, 654
— High-Speed, Theory and Design of, 191, 201*
— Hydraulic, for Cane-Crushing Mills, 354*
— Lubrication of, Effect of Vibration, 203. See 191
— Lubrication of, Heat Transmission in Oil-Coolers, 192
— Main, for Locomotives, 191
— Ring-Oiled, for Centrifugal Pump, 220*
— Roller, Testing Rollers for, 139*
— Thrust, Lubrication of, Michell Principle, 191, 205*. See 726*
Bearings, Thrust, Michell, for Geared-Turbine Steamers, 726*. See 745*
— Thrust, Theory and Design of, 191, 205*
"Bearne," French Battleship, Niclausse Boilers for, 86*. See 73
Beaver, C. J., on Electric Cables, 623
Beilby's Amorphous Cement Theory and the Hardening of Metals, 649, 657*. See 357
Belgian Refugees, Employment for, 516
Bell Bros. Iron Works; Utilisation of Heat in Slag, 428*
Bell, Thomas, The late, 387
Bellini Primary Battery, 154
Bellon Burner for Heavy Oil, 411*
Bells, Electric, for Locomotives, 769*, 772*
Belt Conveyors for Grain, Glasgow Granary, 634*, 693*
— Drive, Lenix System, for Compressors, 408*
Belting, German and Austrian Trade in, 305
Bench-Mark, Transferring Across River, 176*
Bending Stresses in Eccentrically-Loaded Columns, 654, 670, 760*
— Stresses in Ferro-Concrete Beams, 347*
— Stresses in Hooks, &c., 321*, 377*
— Tests. See *Tests* (*Materials*)
Benevolent Fund, Institution of Mechanical Engineers', 501
Bengough, G. D., on the Properties of Copper at High Temperatures, 356*
Bennis, E., and Co., Ltd.; Coal-Handling Plant, Southend Electricity Station, 532*
Benzine Tanks, Use of Grease on Taps for, 63
Benzol and Benzol Mixtures, Trials of Motor-Car Engine with, 706
— Recovery from Coke-Oven Gas, 460
Bergadana Spinning-Frame, 92
Berths, Shipbuilding. See *Shipbuilding*
Beta Particles, Scattering by Magnetons, 581
Bicycles, British and German Trade in, 335
— Motor. See *Motor-Cycle*
Biles, Prof. Sir J. H., on Protection of Battleships from Submarines, 59, 65*. See 80
Binary Alloys. See *Alloys* under *Metallurgy*
Binders for Briquetting Fuels, 126
Binding Wires, Rotor, Stresses in, 719*
Biplanes. See *Aeronautics*
Birmingham Gauge, Steel Sheets and Hoops, 151
— Metallurgical Society, Discussion on Metallurgy and the War, 759
Bitumen, Use in Cable-Laying, 58. See 624
Bituminous Coal, Suction-Gas Plant for, 21
Black Sea-Baltic Canal, Proposed, 254
Blackstone & Co., Ltd.; Portable Oil-Engine, 21*
Blakebrough, J., and Sons; Sluice-Valves for Alexandra Dock, 220*
Blake-Marsden Macadam Plant, 39
Blast-Furnace. See *Furnace*
Bleichert Telpher Railways: Odda Carbide Works, 352*; Charging Blast-Furnaces by, 429*
Blindness, Colour, The Inheritance of, 284, 515
Blow-Pipe, Oxy-Acetylene, Welding Gas-Holders by, 188, 250
— Oxy-Acetylene, Strength of Welds by, 79. See LETTERS, 151, 188, 250
— for Spraying Metals, Schoop Process, 382*
Blower, Turbo, under Test at Parsons' Works, 4
Blue-Prints, Printing, Washing, and Drying-Machine for, 274*. See *Addendum*, 454
Blyth, B. H., on Public Works in Scotland, 574, 602. See LETTER, 654
Blythwood Ruling-Machine, 76
Board, Aeronautical Construction, Proposed, 764
— of Trade and Manufacturers' Inquiries, 311
— of Trade Report, Boiler Explosions Act, 476
— of Trade Report, Explosions in Electric Mains, 58
— of Trade Report, Explosion of Oil-Separator, Staveley Coal and Iron Co., 171
— of Trade Report, Explosion of Steam-Heating Boiler at Southsea, 472
— of Trade Report, Steam-Pipe Explosion at Armstrong, Whitworth and Co.'s Works, 441
— of Trade Statistics, German and Austrian Trade. See *Trade*
Boards, Fibre, Fire-Tests of, 88, 446
Boat Davits, Welin Gear for Swinging, 612*
— Motor. See *Motor-Boat*
— Submarine. See *Warships*
Bogies, Two-Wheeled, for Locomotives, 83*, 740*
Boiler Explosions Act, Report on Working of, 476
— Flues, Experiments on Collapse of, 226. See LETTER, 273
— Furnaces. See *Furnace* and *Stoker*
— German Trade in, 475
— Heated by Blast-Furnace Slag, 428*
— Heating, Explosion at Southsea, 472
— House, Alexandra Dock, 217*
— Locomotive. See *Locomotives*
— Plate, Steel, Cracks in, 84*
— Radiation Losses from, 228
— Repairs, Oxy-Acetylene Welds for, 79. See LETTERS, 151, 188, 250
— Room of Canadian Customs Cruiser, 303*
— Shops: Wallsend Slipway Co.'s Works, 6; North-Eastern Marine Co.'s Works, 27*
— Trials; Measuring Thickness of Fuel on Grates, 227*. See *Erratum*, 259; LETTER, 273

Section A.—Mathematical and Physical Science

Section Reports, 579, 607, 652
Presidential Address, by Prof. F. T. Trouton, on Absorption and Adsorption, 579
Report of Committee on Radiotelegraphic Investigations, 579
Radiotelegraphy, Joint Discussion in Sections A and G, 580
Exact Mechanical Analogy to the Coupled Circuits Used in Wireless Telegraphy, by Prof. T. R. Lyle, 580*
Measurements of the Wave-Length in Air of Electrical Vibrations Associated with a Thin, Straight, Terminated Rod, by Prof. J. A. Pollock, 581
Origin and Nature of the Gamma Rays from Radium, by Sir E. Rutherford, 581
Note on the Magneton as a Scattering Agent of Alpha and Beta Particles, by Prof. W. M. Hicks, 581
Structure of Atoms and Molecules, Joint Discussion in Sections A and B, 607
High-Frequency Spectra, by H. Moseley, 610
Salts Coloured by Cathode Rays, by Prof. E. Goldstein, 610
Scattering of Light by Small and Large Particles of Conducting and Non-Conducting Substance, by A. W. Porter and E. T. Paris, 610
Action of the Juice of Euphorbia Peplus on a Photographic Plate, by Dr. H. G. Chapman and Prof. J. M. Petrie, 611
Photo-Electric Effect of Selenium, by Prof. O. U. Vonwiller, 611
Viscosities of the Halogens (Chlorine, Bromine, Iodine) in the Gaseous State, by Dr. A. O. Rankine, 652
Report of Committee on a Solar Observatory for Australia, 652
Proofs of the Sun's Variability, by Prof. C. G. Abbot, 653
Mount Stromlo Observatory, by P. Baracchi, 653
Australian Longitudes, Discussion on, 653
Motion of the Moon, by Prof. E. W. Brown, 653
Report of Committee on Seismological Investigations, 653
Report of Committee on the Investigation of the Upper Atmosphere, 654
Antarctic Meteorology, Discussion on, 654
Mathematical Papers, 654

Section B.—Chemistry:

Section Reports, 665, 691
Presidential Address by Prof. W. J. Pope, on the Development of Chemistry, 665
Residual Affinity and Co-Ordination, by Prof. G. Morgan and H. W. Moss, 667
Device for the Representation of the Natural Classification of the Elements, by Prof. O. Masson, 691
New Method for Determining the Specific Heats of Liquids, by E. J. Hartung, 691
New Method for the Determination of Vapour Pressures, and an Examination of a Source of Error in Certain Dynamical Methods, by F. H. Campbell, 691
Comparison of the Phenomena of the Occlusion of Hydrogen by Charcoal and by Palladium, by Dr. A. Holt, 691
Corrosion of Iron and Steel by Artesian Water in New South Wales, by Prof. C. E. Fawcitt, 691
Use of Waste Gases of Combustion for Fire Extinction, by G. Harker, 691
Extraction of Radium from Australian Ores, by S. Radcliffe, 691
Influence of Weather Conditions upon the Amount of Nitric Acid and of Nitrous Acid in the Rainfall near Melbourne, by V. G. Anderson, 692
Organic Chemistry, Papers on, 692
Colouring Matters of Certain Marine Organisms, by Dr. A. Holt, 692
Structure of Atoms and Molecules, Joint Discussion in Sections A and B, 607

Section E.—Geography:

Presidential Address by Sir C. P. Lucas, on the Effect of Engineers' Work on the Map of the World, 279

Section F.—Economics and Statistics:

Economics of Marine Fuel, by Prof. A. W. Kirkaldy, 692

Section L.—Education:

Presidential Address by Prof. J. Perry, 307
Address by Prof. H. E. Armstrong, 307

Section M.—Agriculture:

PLATE

I. WALLSEND Slipway and Engineering Co.'s Works: Views of Machine-Shops (facing page 4)

II. Wallsend Slipway and Engineering Co.'s Works: Views of Erecting-Shops (facing page 5)

III. Hull Docks: Hydraulic Tipping-Hoists (Armstrong, Whitworth and Co., Ltd.) (between pages 8 and 9)

IV. Armstrong College, Newcastle-on-Tyne: General View, Engine and Dynamo-Room, and Hydraulic Laboratory (facing page 10)

V. Armstrong College, Newcastle-on-Tyne: Views of Mechanical Laboratory (facing page 11)

VI. Panama Canal: Gatun Power-Station; Views of Pipe-Lines and Spillway (facing page 12)

VII. Panama Canal: Gatun Power-Station; Hydraulic Turbo-Generators and Switch-Gear (facing page 13)

VIII. North-Eastern Marine Engineering Co.'s, Works: Views of Foundry and Machine-Shop (facing page 26)

IX. North-Eastern Marine Engineering Co.'s Works: Views of Erecting-Shop and Boiler-Shop (facing page 27)

X. Alexandra Dock Extension, Newport: Details of Entrance-Lock and Timber Jetties (between pages 36 and 37)

XI. Alexandra Dock Extension, Newport: Views of South Quay Wall and Entrance-Lock (facing page 36)

XII. Alexandra Dock Extension, Newport: Views of Entrance-Lock (between pages 36 and 37)

XIII. Alexandra Dock Extension, Newport: Views of Entrance-Lock (between pages 36 and 37)

XIV. Alexandra Dock Extension, Newport: Views of Entrance-Lock and Concrete-Mixer (facing page 37)

PLATE

XV. Locomotive, 2-8-2 Type, Four-Cylinder, Compound, for Paris, Lyons, and Mediterranean Railway (Société Française de Constructions Mécaniques, Denain (between pages 80 and 81)

XVI. Alexandra Dock Extension, Newport: Details of Lock-Gates (between pages 112 and 113)

XVII. Spanish Battleship "España": Details of 12-In. Gun Barbette Mountings (Sociedad Española de Construccion Naval (between pages 144 and 145)

XVIII. Alexandra Dock Extension, Newport: Details of Rolling-Bridge over South Lock (between pages 178 and 179)

XIX. Alexandra Dock Extension, Newport: Pumping-Plant and Power-Station (between pages 218 and 219)

XX. Canadian Customs Cruiser "Margaret": Elevations and Deck Plans (J. I. Thornycroft and Co., Ltd.) (between pages 246 and 247)

XXI. Calcium Carbide and Cyanamide Works, Odda, Norway: Tyssedal Power-Station; Details of 13,500 H.P. Pelton Wheel and Electric Generator (between pages 268 and 269)

XXII. Canadian Customs Cruiser "Margaret": Arrangement of Machinery (J. I. Thornycroft and Co., Ltd.) (between pages 302 and 303)

XXIII. Ferro-Concrete Bridge at Longtown, Cumberland (between pages 340 and 341)

XXIV. Calcium Carbide and Cyanamide Works, Odda, Norway: Diagrammatic Plan and General View of Plant (facing page 352)

XXV. Calcium Carbide and Cyanamide Works, Odda, Norway: Views of Silos, Kilns, and Carbide Furnaces (between pages 352 and 353)

XXVI. Calcium Carbide and Cyanamide Works, Odda, Norway: Views of Transformers and Regulating Switches (between pages 352 and 353)

XXVII. Sugar-Cane Crushing-Mill (Duncan, Stewart and Co., Ltd.) (facing page 353)

XXVIII. Manhattan Suspension Bridge: General View and View Looking along Central Roadway (facing page 380)

PLATE

XXIX. Manhattan Suspension Bridge: Longitudinal Sections through Anchorages (between pages 380 and 381)

XXX. Manhattan Suspension Bridge: Details of Anchorages and Timber Caissons (between pages 380 and 381)

XXXI. Boring-Mill for Brooklyn Navy Yard: General View (Niles-Bement-Pond Company) (between pages 380 and 381)

XXXII. Boring-Mill for Brooklyn Navy Yard: Views of Castings for Table, Bed, and Cross-Rail (Niles-Bement-Pond Company) (facing page 381)

XXXIII. Steamer "Lutetia," for the Compagnie de Navigation Sud-Atlantique: Deck Plans (Société Anonyme des Chantier et Ateliers de St. Nazaire) (between pages 426 and 427)

XXXIV. Manhattan Suspension Bridge: Details of Towers (between pages 436 and 437)

XXXV. Steamer "Lutetia," for the Compagnie de Navigation Sud-Atlantique: Details of Engines and Turbines (Société Anonyme des Chantier et Ateliers de St. Nazaire) (between pages 470 and 471)

XXXVI. Coal-Handling Plant on the U.S. Naval Collier "Jupiter" (between pages 504 and 505)

XXXVII. Granary at Glasgow Harbour: Sectional Elevations and Plans of Building (between pages 524 and 525)

XXXVIII. Shallow-Draught Steamer "Shu-Hun": Sectional Elevations, Deck Plans, General View, and Details of Propeller in Tunnel (Yarrow and Co., Ltd.) (between pages 572 and 573)

XXXIX. Locomotive, 2-8-8-8-2 Type, Compound, Articulated, for Erie Railroad: General View and Longitudinal Elevation (Baldwin Locomotive Works) (between pages 602 and 603)

XL. Locomotive, 2-8-8-8-2 Type, Compound, Articulated, for Erie Railroad: Cross-Sections (Baldwin Locomotive Works) (between pages 602 and 603)

PLATE

XLI. Locomotive, 2-8-8-8-2 Type, Compound, Articulated, for Erie Railroad: Views and Details of Boiler; Details of Superheater (Baldwin Locomotive Works) (between pages 628 and 629)

XLII. Granary at Glasgow Harbour: Details of Grain-Conveying Machinery (Spencer and Co., Ltd.) (between pages 634 and 635)

XLIII. Locomotive, 2-8-8-8-2 Type, Compound, Articulated, for Erie Railroad: Details of Frames, Saddle, and Articulation System (Baldwin Locomotive Works) (between pages 682 and 683)

XLIV. Granary at Glasgow Harbour: Details of Grain-Conveying Machinery (Spencer and Co., Ltd.) (between pages 694 and 695)

XLV. Locomotive, 2-8-8-8-2 Type, Compound, Articulated, for Erie Railroad: Details of Boiler Bearers, Cylinders, Piston-Valves, Pistons, and Steam-Pipes (Baldwin Locomotive Works) (between pages 738 and 739)

XLVI. Steamers "Ciudad de Buenos Aires" and "Ciudad de Monte Video," with Geared Turbines, for the Argentine Navigation Co., Ltd.: Longitudinal Section and Deck Plans (Cammell Laird and Co., Ltd.) (between pages 744 and 745)

XLVII. Steamers "Ciudad de Buenos Aires" and "Ciudad de Monte Video," with Geared Turbines, for the Argentine Navigation Co., Ltd.: View of Vessel on Trial, and Cross-Sections (Cammell Laird and Co., Ltd.) (facing page 744)

XLVIII. Steamers "Ciudad de Buenos Aires" and "Ciudad de Monte Video," with Geared Turbines, for the Argentine Navigation Co., Ltd.: Views of Dining-Saloon, Awning Deck, and Promenade Deck (Cammell Laird and Co., Ltd.) (between pages 744 and 745)

XLIX. "Steamers "Ciudad de Buenos Aires" and "Ciudad de Monte Video," with Geared Turbines, for the Argentine Navigation Co., Ltd.: Views of Chinese Tea-Room, Social Hall, and State-Room (Cammell Laird and Co., Ltd.) (between pages 744 and 745)

L. Steamers "Ciudad de Buenos Aires" and "Ciudad de Monte Video," with Geared Turbines, for the Argentine Navigation Co., Ltd.: General Arrangement of Machinery (Cammel, Laird and Co., Ltd.) (facing page 745)

LITERATURE.

AERONAUTICS, Flight without Formulæ: Simple Discussions on the Mechanics of the Aeroplane, by Commandant Duchêne, 272
Aeronautics, Principles of Flight, by A. E. Berriman, 163
Alloys, Intermetallic Compounds, by C. H. Desch, 526
Alternating Currents and Alternating-Current Machinery, by D. C. and J. P. Jackson, 484
Ambidexterity and Mental Culture, by H. MacNaughton-Jones, 405
Astronomical, Mathematical, and other Tables, 154
Automobiles, Scientific Tests of, by Dr. A. Riedler, 109

Béton Armé, La Construction en: Theorie et Pratique, by A. V. Magny, 340
Birmingham Commercial Year-Book, 345
Books Dealing with the Useful Arts, 753
Books Received, 110, 163, 174, 215, 259, 273, 297, 406, 485, 569, 661, 720
Bristol University Calendar, 570
British Corporation Register-Book, 98
British War Fleet; Its Inception and Growth throughout the Centuries, by F. T. Jane, 512
Buildings, Fire-Protection in: A Practical Treatise for Engineers, Architects, Surveyors, and Property Owners, by H. G. Holt, 162
Business Life, 461

Chemistry, Industrial, for Engineering Students, by H. K. Benson, 750
Chinese Self-Taught, 233
City and Guilds of London Institute, Report, 652
Coast Sand-Dunes, Sand-Spits and Sand-Wastes, by G. O. Case, 435
Coasts, Maintenance of, by E. Latham, 340
Collieries, Application of Electric Power to, by W. H. Patchell, 162
Commerce, Magnet of, 544
Compounds, Intermetallic, by C. H. Desch, 526
Compressed-Air Practice, by F. Richards, 110
Compressed Air: Treatise on the Production, Transmission, and Use of Compressed Air, by T. Simons, 569
Concrete, Reinforced, Theory and Practice of, by A. V. Magny, 340
Construction en Béton Armé: Théorie et Pratique, by A. V. Magny, 340
Contracts, Effect of War on, by L. Scott, 435
Costs, Engineers', and Economical Workshop Production, by D. Smith and P. C. N. Pickworth, 258

"Daily Mail" Year-Book, 652
Diesel or Slow-Combustion Oil-Engines: A Practical Treatise on the Design and Construction of the Diesel Engine, for the Use of Draughtsmen, Students, and Others, by G. J. Wells and A. J. Wallace-Taylor, 404
Dredging Gold, by T. C. Earl, 339
Dynamics and Statics, by Prof. E. R. Maurer, 484

Electric Power; Application to Mines and Heavy Industries, by W. H. Patchell, 162
Electricity, Photo-: The Liberation of Electrons by Light, with Chapters on Fluorescence, Phosphorescence, Photo-Chemical Actions, and Photography, by H. S. Allen, 174
Electricity, Static, and Magnetism, by J. H. Poynting and Sir J. J. Thomson, 405
Electricity in West Ham, 155
Electrons, Liberation by Light, by H. S. Allen, 174
Elementary Practical Mathematics; with Numerous Exercises for the Use of Students, and Especially of Mechanical and Electrical Engineering Students, by Prof. J. Perry, 214
Enemy, Trading with the: Effect of War on Contracts, by L. Scott, 435
Engineers, British, Directory of, 273
Engineers' Costs and Economical Workshop Production, by D. Smith and P. C. N. Pickworth, 258
Engines, Oil, Slow-Combustion or Diesel: A Practical Treatise on the Design and Construction of the Diesel Engine, for the Use of Draughtsmen, Students, and Others, by G. J. Wells and A. J. Wallace-Taylor, 404
Engine, Steam, Hand-Book on, with Special Reference to Small and Medium-Sized Engines, by H. Haeder, 272
Engines, Steam, by F. Cordier, 272

Factories, Application of Electric Power to, by W. H. Patchell, 162
Factories, Nature and Disposal of Waste Waters from, by H. MacLean Wilson and H. T. Calvert, 215
Ferro-Concrete Construction, Theory and Practice of, by A. V. Magny, 340
Fighting Ships, 259
Fire-Protection in Buildings: A Practical Treatise for Engineers, Architects, Surveyors, and Property Owners, by H. G. Holt, 162
Fleet, the British War; Its Inception and Growth throughout the Centuries, by F. T. Jane, 512
Flight without Formulæ: Simple Discussions on the Mechanics of the Aeroplane, by Commandant Duchêne, 272
Flight, Principles of, by A. E. Berriman, 163
Flying Book, 562
Foreshores, Maintenance of, by E. Latham, 340

Geology; the Petrology of the Igneous Rocks: A Summary of the Modern Theories of Petro-Genesis, a Description of the Rock-Forming Minerals, and a Synopsis of the Chief Types of the Igneous Rocks, and their Distribution, as Illustrated by the British Isles, by F. H. Hatch, 569
Geology, Outlines of Mineralogy, by Prof. G. A. J. Cole, 258
Geology, Structural, by C. K. Leith, 339
Gerard Life-Boat, 756
Girders, Plate, The Design of, by L. E. Moore, 661
Gold-Dredging, by T. C. Earl, 339

Heat and Mechanics, by W. B. Anderson, 173
H.M. Navy; Its Inception and Growth throughout the Centuries, by F. T. Jane, 512
Holiday Guide, 315
Human Motor and the Scientific Bases of Work, by J. Amar, 214
Hydraulics; for Engineering Students and Engineers in Practice, by W. M. Wallace, 526

Igneous Rocks, Petrology of the: A Summary of the Modern Theories of Petro-Genesis, a Description of the Rock-Forming Minerals, and a Synopsis of the Chief Types of the Igneous Rocks and their Distribution, as Illustrated by the British Isles, by F. H. Hatch, 569
Imperial Institute Bulletins, 122, 521
Industrial Chemistry for Engineering Students, by H. K. Benson, 750
Industry, Tin-Plate; with Special Reference to its Relations with the Iron and Steel Industries: A Study in Economic Organisation, by J. H. Jones, 483
Intermetallic Compounds, by C. H. Desch, 526

Junior Institution of Engineers' Journal, 578

Labour, Scientific Bases of, by J. Amar, 214
Life-Saving at Sea, 171
Light, Liberation of Electrons by, by H. S. Allen, 174

Machines à Vapeur, by F. Cordier, 272
Magnetism and Static Electricity, by J. H. Poynting and Sir J. J. Thomson, 405
Maintenance of Foreshores, by E. Latham, 340
Mathematics, Practical, Elementary, with Numerous Exercises for the Use of Students, and Especially of Mechanical and Electrical Engineering Students, by Prof. J. Perry, 214
"Mechanical World" Electrical Pocket-Book, 726
"Mechanical World" Pocket-Diary, 591
Mechanics and Heat, by W. B. Anderson, 173
Mechanics of Particles and Rigid Bodies, by J. Prescott, 750
Mechanics, Technical; Statics and Dynamics, by Prof. E. R. Maurer, 484
Mental Culture and Ambidexterity, by H. MacNaughton-Jones, 405
Metallurgy, Intermetallic Compounds, by C. H. Desch, 526
Mica Deposits in the United States, 757
Mineralogy, Outlines of, for Geological Students, by Prof. G. A. J. Cole, 258
Mineria, Metallurgia, Electricidad e Industrias Quimicas de España, 199
Mines, Application of Electric Power to, by W. H. Patchell, 162
Molecular Physics, by J. A. Crowther, 173
Moteur Humain et le Bases Scientifiques du Travail Professionel, par J. Amar, 214
Motor-Cars, Scientific Tests of, by Dr. A. Riedler, 109

Naval Annual, edited by Viscount Hythe, 94
Naval Architects' Transactions, 461
Navy, The British; Its Inception and Growth throughout the Centuries, by F. T. Jane, 512
Northern Coal, Iron, and Steel Companies, 32

Oil-Engines, Slow-Combustion or Diesel: A Practical Treatise on the Design and Construction of the Diesel Engine, for the Use of Draughtsmen, Students, and others, by G. J. Wells and A. J. Wallace-Taylor, 404
Oil Industry, History and Romance of, by J. D. Henry, 719

Petroleum Industry, History and Romance of, by J. D. Henry, 719
Petroleum Year-Book, 304
Petrology of the Igneous Rocks: A Summary of the Modern Theories of Petro-Genesis, a Description of the Rock-Forming Minerals, and a Synopsis of the Chief Types of the Igneous Rocks and their Distribution, as Illustrated by the British Isles, by F. H. Hatch, 569
Photo-Electricity: The Liberation of Electrons by Light, with Chapters on Fluorescence, Phosphorescence, Photo-Chemical Actions, and Photography, by H. S. Allen, 174
Physics, Molecular, by J. A. Crowther, 173
Physics, Text-Book of, by J. H. Poynting and Sir J. J. Thomson. Parts I. and II., Static Electricity and Magnetism, 405
Physiological Effects of Work, by J. Amar, 214
Pierres Précieuses, by J. Escard, 296
Plate-Girders, The Design of, by L. E. Moore, 661
Pollution of Rivers, Nature and Disposal of Trade-Waste Waters, by H. MacLean Wilson and H. T. Calvert, 215
Power, Electric, Application to Mines and Heavy Industries, by W. H. Patchell, 162
Power for Ship-Propulsion, Estimation of, by Captain C. W. Dyson, 213
Practical Mathematics, Elementary, with Numerous Exercises for the Use of Students and Especially of Mechanical and Electrical Engineering Students, by Prof. J. Perry, 214
Precious Stones, by J. Escard, 296
Principles of Flight, by A. E. Berriman, 163
Propellers, Screw, and Estimation of Power for the Propulsion of Ships, by Capt. C. W. Dyson, 213
Propulsion of Ships, Estimation of Power for, by Capt. C. W. Dyson, 213

Railway Officials, Universal Directory of, 187
Reinforced-Concrete Construction, Theory and Practice of, by A. V. Magny, 340
River Pollution, Nature and Disposal of Trade-Waste Waters, by H. MacLean Wilson and H. T. Calvert, 215
Rocks, Igneous, Petrology of the: A Summary of the Modern Theories of Petro-Genesis, a Description of the Rock-Forming Minerals, and a Synopsis of the Chief Types of the Igneous Rocks and their Distribution, as Illustrated by the British Isles, by F. H. Hatch, 569

Sand-Dunes, Sand-Spits, and Sand-Wastes, by G. O. Case, 435
Scientific Determination of the Merits of Automobiles. Reports I. to IX. of the Laboratory for Motor-Cars at the Royal Technical University, Berlin-Charlottenburg, by Dr. A. Riedler, 109
Screw-Propellers and Estimation of Power for the Propulsion of Ships, by Captain C. W. Dyson, 213
Seashores, Maintenance of, by E. Latham, 340
Serrurerie, Manuel Pratique de, 573
Ship Propulsion, Estimation of Power for, by Captain C. W. Dyson, 213
Ships, British, How to Identity, 446
Shores, Sea, Maintenance of, by E. Latham, 340
Sound: An Elementary Text-Book for Schools and Colleges, by I. W. Capstick, 173
South Kensington Museum, Catalogue, 446
Spanish School Annual, 571
Static Electricity and Magnetism, by J. H. Poynting and Sir J. J. Thomson, 405
Statics and Dynamics, by Prof. E. R. Maurer, 484
Steam-Engines, by F. Cordier, 272
Steam-Engine, Hand-Book on, with Special Reference to Small and Medium-Sized Engines, by H. Haeder, 272
Stones, Precious, by J. Escard, 296
Structural Geology, by C. K. Leith, 339

Technical Mechanics: Statics and Dynamics, by Prof. E. R. Maurer, 484
Technical Schools, Regulations for, 198
Telegraphy, Wireless, Hand-Book of; Its Theory and Practice, for the Use of Electrical Engineers, Students, and Operators, by J. E. Murray, 405
Telegraphy, Wireless, Text-Book on, by R. Stanley, 526
Telegraphy, Wireless, The Wonders of, Explained in Simple Terms for the Non-Technical Reader, by Prof. J. A. Fleming, 297
Tests, Scientific, of Motor-Cars, by Dr. A. Riedler, 109
Tin-Plate Industry, with Special Reference to Its Relations with the Iron and Steel Industries: A Study in Economic Organisation, by J. H. Jones, 483
Trade, Tin-Plate; with Special Reference to its Relations with the Iron and Steel Industries: A Study in Economic Organisation, by J. H. Jones, 483
Trade-Waste Waters, their Nature and Disposal, by H. MacLean Wilson and H. T. Calvert, 215
Trading with the Enemy: The Effect of War on Contracts, by L. Scott, 435

University College Calendar, 573
University College (L.U.) Hand-Book, 223

War-Book, Every Briton's, 440
War, Effect on Contracts, by L. Scott, 435
War Fleet, The British; Its Inception and Growth throughout the Centuries, by F. T. Jane, 512
Waste Waters, Trade, their Nature and Disposal, by H. MacLean Wilson and H. T. Calvert 215
Waters, Trade-Waste, their Nature and Disposal, by H. MacLean Wilson and H. T. Calvert, 215
Wireless Telegraphy, Hand-Book of; Its Theory and Practice, for the Use of Electrical Engineers, Students, and Operators, by J. E. Murray, 405
Wireless Telegraphy, Text-Book on, by R. Stanley, 526
Wireless Telegraphy, The Wonders of, Explained in Simple Terms for the Non-Technical Reader, by Prof. J. A. Fleming, 297
Wonders of Wireless Telegraphy, Explained in Simple Terms for the Non-Technical Reader, by Prof. J. A. Fleming, 297
Work, Physiological Effect of, by J. Amar, 214
Works, Application of Electric Power to, by W. H. Patchell, 162
Works, Nature and Disposal of Waste Waters from, by H. MacLean Wilson and H. T. Calvert, 215

LETTERS TO THE EDITOR.

(Illustrated Subjects are Marked with an Asterisk after the Number of the Page.)

ACCUMULATOR Motor-Cars. See *Electric-Vehicle Association*
Acetylene Welding. See *Welding*
Aerodynamics, Wind Pressure on Cylindrical Bodies. F. S. Cripps, 301*
Air-Filters, Comparisons of Wet and Dry Types, Heenan and Froude, Ltd., 531
Air Pressure on Cylindrical Bodies. F. S. Cripps, 301*
America, Central and South, Social and Economic Conditions. C. R. Enock, 132; The Writer of the Review, 132
America, Electric-Vehicle Association of. See *Electric*
Arts, German Achievements in. J. H. Jay, 531; H. D. Hibbard, 587
Austrian-Owned British Patents and the War. See *Patents*
Autogenous Welding. See *Welding*
Automobiles. See *Motor-Cars*

Banks, Influence on Industries. Robinson, Williams, and Burnands, 712; E. J. Fox, 725; C. T. A. Hanssen, 752; A. Percy, 752
Battleship Design, Advantages of Large Guns. G. Quick, 531
Bearings, Crank-Shaft, Motor-Car Engines, Design of. A. E. Parnacott, 654
Belgian Refugees, Employment for. H. T. Vane, for D. Napier and Son, Ltd., 516
Bending Stresses in Eccentrically-Loaded Columns. See *Columns*
Blow-Pipe, Oxy-Acetylene. See *Welding*
Boiler-Flues, The Collapse of. R. V. Southwell, 273
Boiler-Plates, Steel, Cracks in. R.J.N.W., 84*
Boiler Trials, Report of Institution of Civil Engineers' Committee on. C. Thomson, 273
Boiler Trials, Weighing Fuel on Grate. C. Thomson, 273
Boilers, Yarrow, Trials with Kermode Oil-Fuel System. J. J. Kermode, 712
Bridges, Rolling Loads on, Influence Lines for G. P. Manning, 85
British and German Trade Competition. See *Trade*
British Manufacturers, Financial Assistance by Banks. See *Banks*
British Patents and Foreign Patentees. See *Patents*
Brittleness of Steel Boiler-Plates. R. J. N. W., 84*
Buildings, Steel-Framed, L.C.C. Regulations for. See *Columns, Eccentrically Loaded.*

Catenary, Hydrostatic, Solution of. H. M. Gibb, 85*; G. P. Manning, 151*
Central and South America, Social and Economic Conditions. C. R. Enock, 132; The Writer of the Review, 132
Civil Engineers, Institution of, Report on Conduct of Steam-Engine and Boiler Trials. C. Thomson, 273
Collapse of Short Tubes. R. V. Southwell, 273
Colleges, Technical, Marking Laboratory Equipment in. R. Riddell, 273
Columns, Design of, Publication of Gordon's Formula, S. 425
Columns, Eccentrically-Loaded, Stresses in. Enquirer, 654; A. H. Shield, 670
Condensers, Design for Steam-Turbines. S. L. Pearce, 752
Contractors, Financial Assistance by Banks. See *Banks*
Corthesy-Dickson Steam-Turbine. Engineer-Captain A. E. Tompkins, 151
Cracks in Steel Boiler-Plates. R. J. N. W., 84*
Crank-shaft Bearings, Motor-Car Engines, Design of. A. E. Parnacott, 654
Cutting Properties of Metals and Hardness Tests. See *Hardness*
Cylinders, Short, Thin, the Collapse of. R. V. Southwell, 273
Cylindrical Bodies, Wind Pressure on. F. S. Cripps, 301*

Dickson-Corthesy Steam-Turbine. Engineer-Captain A. E. Tompkins, 151
Dredgers, Suction, used at Liverpool. W. W. Wilkes, for Gwynnes, Limited, 132
Dynamometer, Transmission, with Visible Scale. J. A. Smith, 712

Eccentrically-Loaded Columns. See *Columns*
Education, Methods of Marking Laboratory Equipment, R. Riddell, 273
Education, Scientific Advisory Committee, Sheffield University. W. E. S. Turner, 587
Education, Suggested Suspension of Examinations during War. An Aged Engineer, 301
Electric-Vehicle Association of America, Annual Convention at Philadelphia. F. Ayton, 188
Electrolytic Iron. G. C. Lloyd, for Iron and Steel Institute, 455
Engineering Examinations, Suggested Suspension during War. An Aged Engineer, 301
Engineering Laboratories, Methods of Marking Equipment. R. Riddell, 273
Engineers' Work in the War. J. G. Carew-Gibson, 222
Engines, Petrol, Motor-Car, Design of Crank-Shaft Bearings. A. E. Parnacott, 654
Engines, Steam, Trials of, Report of Institution of Civil Engineers' Committee on. C. Thomson, 273
European War, British and German Trade Competition. See *Trade*
European War, British Patents and Foreign Patentees. See *Patents*
European War, Emergency Workers' Hours B. F. W., 425
European War, Employment of Belgian Refugees. H. T. Vane, for D. Napier and Son, Ltd., 516
European War, Influence of Banks on Industry. See *Banks*
European War, Status of Tool-Designers. J. H. J., 712
European War, Suggested Suspension of Engineering Examinations. An Aged Engineer, 301
European War, Work for Engineers. J. G. Carew Gibson, 222
Examinations, Engineering, Suggested Suspension during War. An Aged Engineer, 301
Export Trade. See *Trade*

Filters, Air, Comparisons of Wet and Dry Types. Heenan and Froude, Ltd., 531
Financial Assistance of Manufacturers by Banks. See *Banks*
Flues, Boiler, Collapse of. R. V. Southwell, 273
Fuel, Oil. See *Oil Fuel*

Gas-Holders, Oxy-Acetylene Welding of. See *Welding*
Gas-Holders, Wind-Pressure on. F. S. Cripps, 301*
German Achievements in Science and Arts. J. H. Jay, 531; H. D. Hibbard, 587
German and British Trade Competition. See *Trade*
German Navy, Use of Oil Fuel in. J. J. Kermode, 712
German-Owned British Patents and the War. See *Patents*
Gordon's Formula for Columns, Publication of. S., 425
Great North of Scotland Railway, Exchange of Tablets on. J. Manson, 654
Guns, Advantages of Large-Calibre. G. Quick, 531

Hardness Tests, Theory of. A. F. Shore, 84; R. H. Greaves, 132
Hydrostatic Catenary, Solution of. H. M. Gibb, 85*; G. P. Manning, 151*

Industrial Banks. See *Banks*
Influence-Lines for Rolling Loads on Bridges. G. P. Manning, 85
Institution of Civil Engineers, Report on Conduct of Steam-Engine and Boiler Trials. C. Thomson, 273
Iron, Electrolytic. G. C. Lloyd, for Iron and Steel Institute, 455

Jets, Steam, The Reaction of. Engineer-Captain A. E. Tompkins, 151
Jig-Designers, Status in the War. J. H. J., 712

Kermode Oil-Fuel System, Trials of Yarrow Boilers with. J. J. Kermode, 712

Laboratory Equipment, Methods of Marking. R. Riddell, 273
Liquid Fuel. See *Oil Fuel*
Liverpool, Suction-Dredgers used at. W. W. Wilkes, for Gwynnes, Ltd., 132
London County Council Regulations, Steel-Framed Buildings. See *Columns, Eccentrically Loaded*

Machine-Tools, The Finish of. A. H. Shield, 425
Machinery, Furtherance of British Export Trade in. Canuck, 486
Manufacturers, Financial Assistance by Banks. See *Banks*
Marking Laboratory Equipment. R. Riddell, 273
Mathematics, Solution of Hydrostatic Catenary. H. M. Gibb, 85*; G. P. Manning, 151*
Mersey Docks and Harbour Board, Suction Dredgers used by. W. W. Wilkes, for Gwynnes Ltd., 132
Metals, Cutting Properties of, and Hardness Tests. See *Hardness*
Metropolitan Railway, Paris, Street Subsidences. H. J. de Cordemoy, 85
Motor-Cars Accumulator. See *Electric-Vehicle Association*
Motor-Cars, Design of Crank-Shaft Bearings. A. E. Parnacott, 654

Naval Warfare, Advantages of Large Guns. G. Quick, 531
Navy, German, Use of Oil-Fuel in. J. J. Kermode, 712
Nozzles, Flow of Steam Through, Reaction of Jets. Engineer-Captain A. E. Tompkins, 151

Oil-Fuel, Kermode System, Trials of Yarrow Boilers with. J. J. Kermode, 712
Oil-Fuel, Use in German Navy. J. J. Kermode, 712
Oxy-Acetylene Welding. See *Welding*

Paris Street Subsidences. H. J. de Cordemoy, 85
Patents, British, and Foreign Patentees during War. A. E. Tucker, 327; A. L. Annison, 327, 360
Petrol-Engines, Motor-Car, Design of Crank-Shaft Bearings. A. E. Parnacott, 654
Philadelphia, Annual Convention of Electric-Vehicle Association. See *Electric*
Pillars. See *Columns*
Plates, Boiler, Cracks in. R. J. N. W., 84*
Pressure, Wind, on Cylindrical Bodies. F. S. Cripps, 301*
Professional Examinations, Suggested Suspension during War. An Aged Engineer, 301
Projectiles, Advantages of Large Size. G. Quick, 531

Railway, Paris Metropolitan, Street Subsidences. H. J. de Cordemoy, 85
Railways, Single-Line, Exchange of Tablets on. J. Manson, 654
Reaction of Steam Jets. Engineer-Captain A. E. Tompkins, 151
Regulations, L.C.C., for Steel-Framed Buildings. See *Columns, Eccentrically-Loaded*
Republics of Central and South America. C. R. Enock, 132; The Writer of the Review, 132
Road Subsidences in Paris H. J. de Cordemoy. 85
Rolling Loads on Bridges, Influence Lines for. G. P. Manning, 85
Rules, L.C.C., for Steel-Framed Buildings. See *Columns, Eccentrically-Loaded*

Science and Arts, German Achievements in. J. H. Jay, 531; H. D. Hibbard, 587
Scleroscope Hardness Tests. See *Hardness*
Scotch Railways, Exchange of Tablets on. J. Manson, 654
Shafts, Measurement of Torque by Optical Means. J. A. Smith, 712
Sheffield University, Scientific Advisory Committee. W. E. S. Turner, 587
Shells, Advantages of Large-Size. G. Quick, 531
Shore Scleroscope, Hardness Tests. See *Hardness*
Short Tubes, Collapse of. R. V. Southwell, 273
Single-Line Railways, Exchange of Tablets on. J. Manson, 654
Smith's Torsion-Meter with Visible Scale. J. A. Smith, 712
South America. Social and Economic Conditions in. C. R. Enock, 132; The Writer of the Review, 132
Steam Consumption of Turbines, Effect of Vacuum on. S. L. Pearce, 752
Steam-Engines. See *Engines*
Steam-Jets, The Reaction of. Engineer-Captain A. E. Tompkins, 151
Steam-Turbines. See *Turbines*
Steel Boiler-Plates, Cracks in. R. J. N. W., 84*
Steel-Framed Buildings, L.C.C. Regulations for. See *Columns, Eccentrically-Loaded*
Steel, Hardness Tests and Cutting Properties of. See *Hardness*
Storage Battery Motor-Cars. See *Electric-Vehicle Association*
Street Subsidences in Paris. H. J. de Cordemoy, 85
Stresses in Eccentrically-Loaded Columns. See *Columns*
Struts. See *Columns*
Suction Dredgers Used at Liverpool. W. W. Wilkes, for Gwynnes, Ltd., 132

Tablets, Exchange of, on Single-Line Railways. J. Manson, 654
Technical Colleges, Marking Laboratory Equipment in. R. Riddell, 273
Tests, Hardness. See *Hardness*
Tests of Yarrow Boilers with Kermode Oil-Fuel System. J. J. Kermode, 712
Tool-Designers, Status in the War. J. H. J., 712
Torque Measurement by Optical Means. J. A. Smith, 712
Torsion-Meter with Visible Scale. J. A. Smith, 712
Trade Competition, British and German, Finish of Machine-Tools. A. H. Shield, 425
Trade Competition, British and German, Furtherance of British Export Trade in Machinery, &c. Canuck, 486
Trade Competition, British and German, Importance of Sales Departments. V. H. Coates, 455, 571
Trade Competition, British and German, Influence of Banks on Industry. See *Banks*
Trade Competition, British and German, Scientific Advisory Committee of Sheffield University. W. E. S. Turner, 587

Rome, Ancient, Water Supply of, 507
Truro City Supply, 276

PATENT RECORD.

The Patent Index is classified under the following sub-titles:—AGRICULTURAL APPLIANCES; ELECTRICAL APPARATUS; GAS-ENGINES, PRODUCERS, HOLDERS, &c.; GUNS AND EXPLOSIVES; HYDRAULIC APPARATUS; LIFTING AND HAULING APPLIANCES; MACHINE AND OTHER TOOLS, SHAFTING, &c.; MILLING AND SEPARATING MACHINERY; MINING, METALLURGY, AND METAL-WORKING; MISCELLANEOUS; MOTOR ROAD VEHICLES; PRINTING AND ALLIED MACHINERY; PUMPS; RAILWAYS AND TRAMWAYS; SHIPS AND NAUTICAL APPLIANCES; STEAM-ENGINES, BOILERS, EVAPORATORS, &c.; TEXTILE MACHINERY; AND VEHICLES.

SUBJECT MATTER.

Aeronautics:

433, 690
Aeroplanes. Vickers, Ltd., and G. H. Challenger, 433
Biplanes. H. L., A. E. and H. O. Short, 690

Agricultural Appliances:

172
Implements. F. M. Waller, 172

Electrical Apparatus:

108, 141, 172, 207, 320, 402, 463, 493, 522, 605, 659, 689, 744
Accumulators, Charging. J. G. P. Thomas and the Thomas Transmission, Ltd., 172
Accumulators, Charging. H. Leitner, 141
Balances, Magnetic. R. W. Paul, 522
Cable-Troughs, Earthenware. H. L. Doulton and C. E. Morris, 605
Commutator Motors, Alternating-Current. Siemens-Schuckertwerke G.m.b.H., 493
Cooking-Stoves, Electric. Siemens-Schuckertwerke G.m.b.H., 463
Dynamo-Electric Machines. E. Rosenberg, 320
Heating Apparatus. A. F. Berry, 463
Insulators. E. P. B. Estler, 744
Lamps, Mercury-Vapour. E. E. Darmois and M. A. E. Leblanc, 689
Metals, Electric Soldering. A. E. G., 463
Switches, Electric. F. B. Holt and H. Smith, 605
Switches, Electrical. A. P., G. C., and P. A. Lundberg and G. Pegg, 108
Telegraphy. W. Judd, B. Davies and the Eastern Telegraph Co., Ltd., 141, 172
Telegraphy, Duplex. F. Ryan and the Eastern Telegraph Co., Ltd., 605
Voltage-Regulators A. H Olmsted, 744
Wireless Apparatus. G. E. Heyl and T. T. Baker, 402
Wireless Telegraphy. J. A. Fleming, 659
Wireless Telegraphy. Marconi's Wireless Telegraph Co., Ltd., and C. P. Ryan, 207
Wireless Telegraphy. The Radio-Signal Co., Ltd., W. H. Shephard and A. E. McKechnie, 207

Gas-Engines, Producers, Holders, &c.:

108, 141, 172, 207, 292, 320, 402, 463, 493, 522, 550, 659, 744, 774
Bunsen Burners. J. G. Watkinson and P. H. Fletcher, 493
Furnaces, Regenerative Gas. F. K. Siemens, 522
Governors, Gas. J. F. Simmance and J. Abady, 141
Internal-Combustion Engines. The Austin Motor Co., Ltd, and H. Austin, 493
Internal-Combustion Engines. E. E. Bentall and G. C. Bingham, 292
Internal-Combustion Engines. J. and H. K. Boyle and A. L. and C. B. Redrup, 659
Internal-Combustion Engines. K. I. Crossley and W. Le P. Webb, 774
Internal-Combustion Engines. Crossley Motors, Ltd., and A. W. Reeves, 463
Internal-Combustion Engines. C. G. Eden and Hans Renold, Ltd., 550
Internal-Combustion Engines. T. E. Halliday, 744
Internal-Combustion Engines. D. A. Pearson, 402
Internal-Combustion Engines. Scotts' Shipbuilding and Engineering Co., Ltd., and J. Richardson, 108
Internal-Combustion Engines. Vickers, Ltd., and G. Bourcier, 141, 172
Internal-Combustion Engines. Willans and Robinson, Ltd., and J. M. Ferguson, 522
Oil-Engines. E. Gardner, 207
Retorts, Discharging or Charging. Drakes, Ltd., and A. Dobson, 320
Sparking-Plugs. F. H. Bluemel and Bluemel Bros., 744

Guns and Explosives:

141, 346, 402, 433, 493, 522, 605, 659, 774
Breech-Loading Guns. Sir A. T. Dawson and G. T. Buckham, 522, 659
Bullets, Impact Illuminating. Winchester Repeating Arms Co., 659
Cupolas for Ordnance. Société Anon. John Cockerill and E. Ternstrom, 774
Mines, Submarine. Harlé et Cie., 605
Ordnance, Sighting of. Sir A. T. Dawson and G. T. Buckham, 346
Projectiles. Sir W. G. Armstrong, Whitworth and Co., Ltd., and S. M. Murray, 433

Guns and Explosives—*continued.*
Projectiles. R. P. R. Embury and R. H. S. Bacon, 141
Sighting of Stationary Ordnance. Fried. Krupp A.-G., 493
Torpedoes, Automobile. R. S. P. Hornby, F. Hore, and F. E. Smith, 402
Torpedoes, Automobile. E. Schneider, 522

Hydraulic Machinery:

493
Valves for Hydraulic Systems. J. Stone and Co., Ltd., F. J. Pike, and H. Neville, 493

Lifting and Hauling Appliances:

292
Cranes. Babcock and Wilcox, Ltd., and F. W. Hollick, 292
Winding-Engines. The Butterley Co., Ltd., and C. E. Drabble, 292

Machine and other Tools, Shafting, &c.:

142, 208, 320, 433, 605, 659, 689, 718
Bearings for High-Speed Spindles. The Auto-Machinery Co., Ltd., and H. S. Wood, 689
Bevel-Gear Wheels. L Renault, 605
Clutch and Brake Mechanism. C. H. de Kusett, 660
Gear-Cutting Machines. The Hon. Sir C. A. Parsons, A. Q. Carnegie, and S. S. Cook, 142
Lathe-Carrier. A. Ransome and Co., Ltd., and W. V Jones, 605
Roller-Bearings. S. Z. de Ferranti, 689
Shafts, Anti-Frictional Mounting. A. J. Hollick and W. Kneen, 659
Thrust-Bearings. A. J. Hollick and W. Kneen, 605
Tool-Chucks. Electric and Ordnance Accessories Co., Ltd., and L. M. Ellis, 320
Toothed Gearing. C. Marsden and the Power-Plant Co., Ltd., 718
Turret Lathes. A. Herbert and P. V. Vernon, 208, 320
Variable-Speed Drive. R. H. S. Bacon and W. S. Roe, 433
Wood-Working Machines. Thos. Robinson and Son, Ltd., and P. S. Robinson, 208

Mining, Metallurgy, and Metal-Working:

142, 550
Block-Links, Manufacture of. C. G. Renold and Hans Renold, Ltd., 550
Furnaces. C. D. McCourt, 142
Furnace, Smelting, Electrical. Fried. Krupp A.-G., 550
Hammers, Drop. B. and J. Brett, 142

Miscellaneous:

172, 660, 690, 718
Accelerometers. J. S. Drewry, 718
Centering for Concrete Floors. C. Tomkinson and J. T. Williams. 172
Gauging Instruments. J. A. Prestwich, 690
Heating Apparatus. P. St. G. Kirke and Bonecourt Surface Combustion, Ltd., 690
Liquid-Depth Gauge. K. Rotherham, 718
Meters for Liquids. Société L'Aster, 660
Torsion-Testing Machine. W. E. Lilly, 660

Motor Road Vehicles:

108, 207, 292, 346, 402, 433, 494, 606, 689, 744
Axles, Rear, Motor Vehicle. Albion Motor-Car Co., Ltd., and T. B. Murray, 494
Cycles, Motor. H. S. Yoxall and J. J. Richardson, 689
Road Vehicles, Motor. J. F. Henderson and Albion Motor-Car Co., Ltd., 346
Road Vehicles, Motor. H. Spurrier, 207
Road Vehicles, Motor. E. Williams, 402
Road Vehicles, Motor-Propelled. A. M. and E. Arter and Marshall Arter, Ltd., 108
Road Vehicles. H. M. Butler, 292
Road Vehicles, Motor. L. E. Cowey, 207
Road Vehicles, Motor. Société Th. Schneider et Cie., 689
Seats, Folding. G. H. Lanchester and the Lanchester Motor Co., Ltd., 494
Shaft-Couplings. Société Anonyme des Automobile Unic, 689
Speed-Indicators. W. O. Smith, 744
Wheel-Rims. P. B. Bosworth, 292
Wheels, Vehicle. P. B. Bosworth, 606

Printing and Allied Machinery:

689
Printing-Machines. E. J. Smith, 690
Typographical Machines. Linotype and Machinery, Ltd., and J. R. Burgess, 689

Pumps:

108, 142, 346, 463, 494, 718
Air-Compressors. P. and G. H. T. Rayner, 463
Centrifugal Pumps. Bertrams, Ltd., and G. Robertson, 108
Centrifugal Pumps. S. C. Davidson, 718
Centrifugal Pumps. G. and J. Weir, Ltd., and J. Petermoller, 494
Pumps. James Simpson and Co., Ltd., and H. D. Shrimpton, 142
Turbo-Compressors. A.-G. Brown, Boveri et Cie., 346

Railways and Tramways:

208, 346, 433, 463, 494, 606, 774
Axle-Bearings, Locomotive. R. Jelley, 606
Brake-Shoes. Metropolitan Carriage, Wagon and Finance Co., Ltd., and E. Squires, 774
Current-Collectors. Allgemeine Electricitäts Gesellschaft, 494
Keys, Metal, for Rails. F. J. Talbot, 463
Locomotives. H. A. Stenning and Schmidt's Superheater Co. (1910), Ltd., 433
Permanent-Way. George Turton Platts and Co., Ltd., and A. R. Stuart, 208
Point-Operating Appliances, Railway. A. and C. B. Lines, 494
Railless Traction. E. M. Munroe and the R. E. T. Construction Co., Ltd., 346
Rolling-Stock. The Metropolitan Carriage, Wagon, and Finance Co., Ltd., H. C. Grigg, and N. Swift, 434
Rolling-Stock. G. H. Sheffield and McKerrow and Co., Ltd., 464
Signalling, Railway. H. W. Firth and F. W. Leake, 433

Ships and Nautical Appliances:

208, 464, 494, 660, 718
Compass-Bowls. W. D. Whyte, 660
Dredgers, Suction. F. Lobnitz, 208
Ice-Breaking Steamships. Sir W. G. Armstrong, Whitworth and Co., Ltd., and E. L. Orde, 494
Rudder-Pintles. J. M. Ramsay, 718
Submersible Boats. Vickers, Ltd., and James McKechnie, 464

Steam-Engines, Boilers, Evaporators, &c.:

208, 402, 434, 464, 550, 606, 660, 744, 774
Condensers. A. G. Brown, Boveri and Co., 660
Condensers. D. B. Morison, 744
Feed-Water Heaters. D. B. Morison, 464, 660
Furnaces. H. McPhail, 606
Furnaces, Chain-Grate. E. Bennis, 208, 402
Generators, Gas-Fired Steam. P. St. G. Kirke and Bonecourt Surface-Combustion, Ltd., 434
Generators, Steam. Babcock and Wilcox, Ltd., and J. H. Rosenthal, 434
Generators, Steam. Circulators, Ltd., and H. Schofield, 774
Generators, Steam. Edward Makin, 550
Superheaters, Steam. T. Sugden, 464
Turbines. General Electric Company, 606
Turbines, Steam. H. Mensforth, 464
Valves. J. Clayton and R. Taylor, 434

Textile Machinery:

208, 320, 434, 550, 718, 774
Cop-Winding Machines. J. Higginson and H. Arundel, 208
Loom-Shedding Motions. Barritt and West, Ltd., and E. T. West, 320
Looms. R. E. Starkie, 718
Looms. I. Walton, 550
Mules, Self-Acting. J. Pickford, 208
Ring-Spinning. T. Cotton and T. W. Stead, 434
Thread-Guides. J. L. Rushton, 774

NAMES OF PATENTEES.

Abady, J., and another. Gas-Governors, 141

the requirements of Messrs. Armstrong, Messrs. Asquith have designed and provided machines carrying high-speed radial drills, supported on a bridge travelling on rails between which the plate to be drilled can be supported, so that the work can be completed on the longest of plates without any movement of the plate. Another notable tool is a plate-edge planer, which is designed so that the beam with hand-screw and hydraulic holding-down clamps can be raised, in order to enable turbine-lifting girders, up to 2 ft. 3½ in. deep, to be planed. The punching and shearing-machines, and any others where work has to be supported during operations, are provided with 8-ton cranes, of 23-ft. rake, and the smaller machines with 5-ton cranes, of 20-ft. rake. The practice is adopted of laying out and drilling

In the range of buildings behind the fitting-out wharf the blacksmiths' shop comes first. It is 300 ft. long by 80 ft. wide by 30 ft. high, and included in its equipment is a gas-fired reversing regenerative forging-furnace and an annealing furnace. At the west end of this building is the blacksmiths' fitting-shop for the manufacture of ladders, gratings, mess-racks, &c.

A very important department is the fitting-shop, a building 300 ft. long by 132 ft. wide. Under the same roof there is arranged a tool department, with stores and a valve-testing shop. Above these are the riggers' loft and sail-makers' shop. The remainder of the building is divided into three bays, the largest of 40 ft. 9 in. span. Two of the bays accommodating the larger machine-tools are

another to benches, while a third is given up to the erection of furniture, cabins, &c. In the galleries there are to be pattern and model-makers' shops. In close proximity to the joiners' shop is a saw-mill, which is now in process of erection. It is a building 120 ft. long, 82 ft. 6 in. wide, and 26 ft. high. Adjoining it is a boat-building shed of the same length, 71 ft. in width and 16 ft. in height. An annexe to the saw-mill is being arranged as a saw-sharpener's shop. Needless to say, the equipment in these departments corresponds in modernity of design and adequacy of power with that in the other departments of the works. To the rear of the saw-mill are timber-drying and storing-sheds. The logs will be lifted from the river by the 30-ton crane

bulkheads and decks in position in the platers' shed, as this greatly facilitates the preparation of the work for subsequent erection in the ship.

It will be seen that the angle and frame shop is at the head of the largest of the shipbuilding berths. The material, brought by rail, is stored behind the building, and here is installed a gantry-crane of 5 tons capacity and 120-ft. span, for disposing of bars in the racks or lifting them on to railway-trucks to be conveyed to the furnaces. The furnaces are all gas-fired. That for angles is double-ended, 90 ft. long by 4 ft. wide, with bending blocks at each end, while those for plates are 36 ft. by 13 ft. and 25 ft. by 10 ft. 6 in. The equipment of the frame shop, which is 300 ft. long by 380 ft. wide, and about 30 ft. high, is thoroughly modern. Forming part of the same building, but separated by a division wall, is the anglesmiths' shop, where also is a gas-fired furnace and a powerful hydraulic press for stamping out doors, &c.

traversed by 10-ton cranes. The mechanical equipment of the department is very comprehensive, and includes several tools of special design, but we prefer to postpone a detailed description until we can illustrate them. The next building is given up to stores, there being not only general stores, but special Admiralty stores, electricians' workshop, yard electric stores, ship electric stores, cable and rope stores, all embraced in a building 300 ft. long, 120 ft. wide, and 23 ft. 6 in. high, and equipped with cranes for the quick movement of supplies required in the ships during the process of fitting out.

The wood-working departments occupy the remainder of the buildings in the range behind the wharf. The joiners' shop is, like the other buildings, 300 ft. long, and its width of 100 ft. is divided into three bays, with a gallery round four sides of the interior of the building. One of the ground-floor bays is devoted to machinery,

traversing the main fitting-out wharf, and will be placed on railway trucks or laid on the wharf under a gantry forming an extension of the overhead crane-track in the saw-mill, so that the logs can be moved to any of the saws or placed on trucks to be delivered where required.

At present the plumbers, coppersmiths, and sheet-iron workers are temporarily housed, because the site which the shops will ultimately occupy is required in connection with the ferro-concrete work in the yard. This site is between the 1000-ft. ship-berth and the river. The main building, in which they will be accommodated, will be 431 ft. long by 62 ft. 6 in. wide, while adjoining them is the power-house and other departments.

The buildings generally are of a very substantial character, and the roofs of the smaller shops are on the saw-tooth principle, with abundance of light. The platers' shed, which is exceptional, is built up of columns at 80-ft. centres longitudinally, with

TESTING TURBO-DYNAMOS AT THE HEATON WORKS OF MESSRS. PARSONS & CO., LTD.

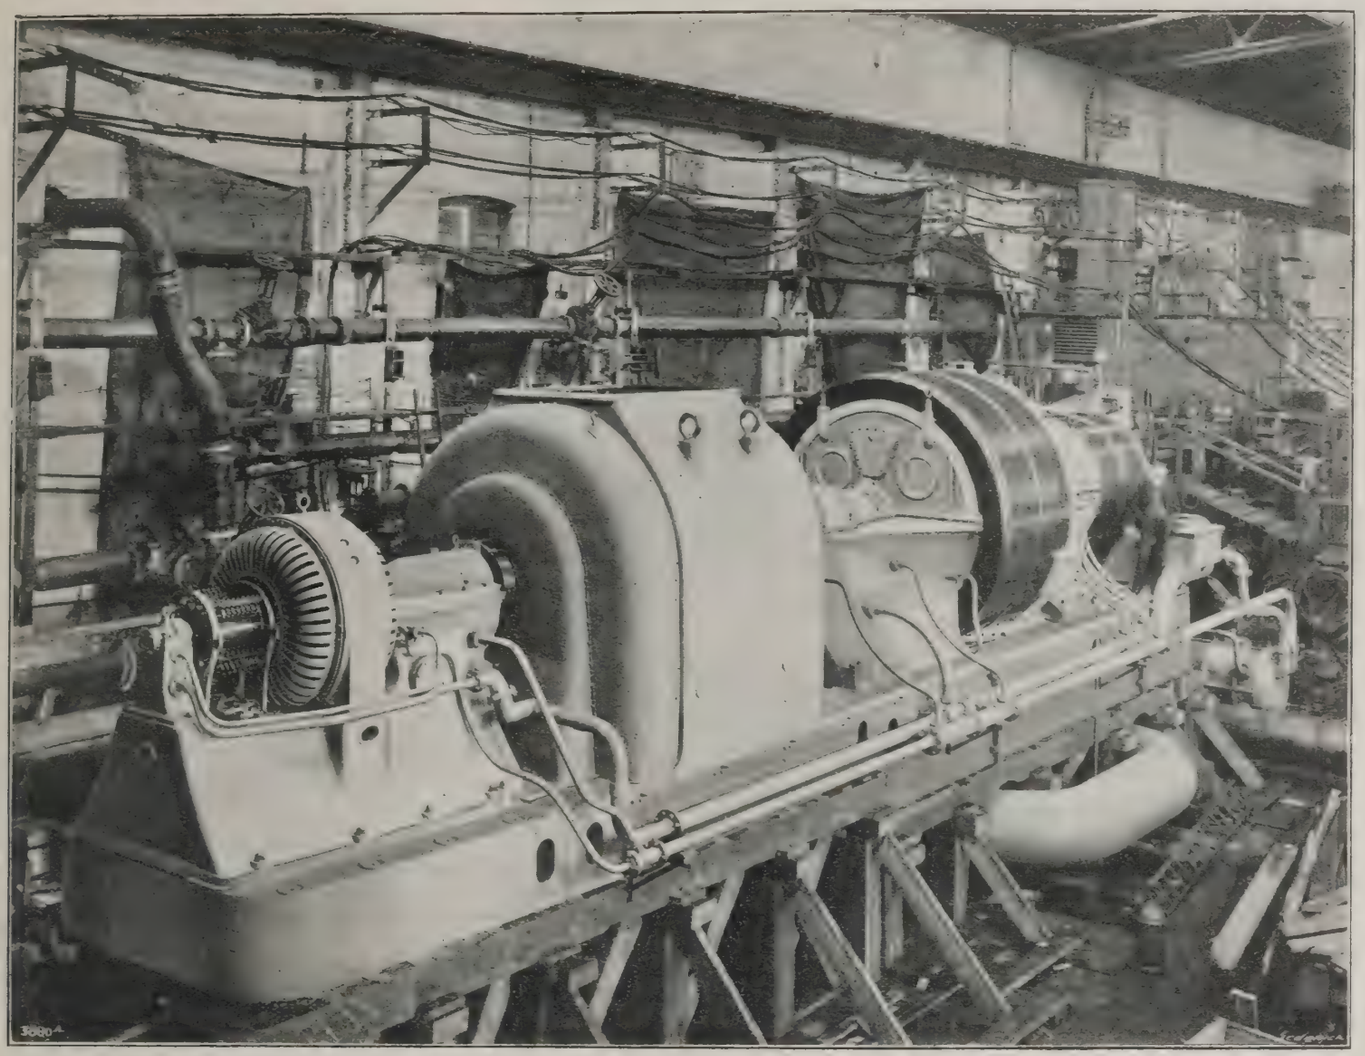

FIG. 1. GENERAL VIEW OF TESTING DEPARTMENT.

four lines of box-shaped lattice girders extending the full length of the building, and carrying the superstructure and tracks for the travelling gantry cranes. These also carry the roof principals, and the roof itself is entirely of Mellowe's patent glazing, as is also the greater part of the side-walls, with a slight portion of corrugated steel.

As regards the power, this is taken from the mains of the Newcastle Electric Supply Company at 6000 volts and 40 cycles per second, and transformed to 440 volts for distribution to the various shops. Primary consideration was given to the problem of obviating a complete breakdown through stoppage of the supply, and at the same time to the desirability of reducing the length of low-tension cable. It was therefore decided that there should be three sub-stations situated at the most convenient points in the works for the distribution of power to the various departments. Thus, the north sub-station supplies buildings grouped in its neighbourhood, behind the fitting-out quay; the central sub-station supplies the machines in the power stations, such as hydraulic pumps, air-compressors, &c.; and the third sub-station is for the machines in the platers' shed and other general purposes in the neighbourhood. As already stated, there are subsidiary transformer stations at the building-berths. In addition to these, transformers have been placed at convenient positions throughout the works, to reduce the current to 110 volts for lighting purposes. The main supply is brought into both the north and south sub-stations in duplicate, and each of these is connected to the power-house, which also constitutes a sub-station. By this arrangement the whole yard can be completely supplied through either the north or south sub-station, and thus the possibility of accident involving the complete failure of supply is reduced to an absolute minimum. The whole of the pipes carrying the electric cables, pressure water, supply water, air for pneumatic purposes, &c., throughout the yard, have been arranged in a common trench, and where these pass under rail way tracks concrete walls have been built to support the railway track over the pipes.

There are about 4½ miles of drains and sewers throughout the works, while the drains on the slopes between the high-level ground behind the works and the level of the yard itself extend collectively to about 9½ miles. Throughout the works there are about 10 miles of railway track, laid with 90-lb. flat-bottomed rails, and with nearly 170 points and crossings. There are a large number of locomotives throughout the works, in addition to 10-ton travelling cranes with 45-ft. jibs. We hope, however, when the works are completed, to return to the subject and give full details and illustrations.

THE TESTING OF TURBO-DYNAMOS.

THE success of the Parsons turbine-driven electric machinery is largely a consequence of the experimental work done at the Heaton Works, and the care continuously exercised to ensure that the specified or guaranteed conditions are fulfilled before the manufactures leave the establishment. From time to time experimental appliances have been evolved, and now the department, which has been rearranged, is not only comprehensive, but admits of extensive and accurate testing work being done. Provision is made for testing at full load for several hours continuously turbo-dynamos having an output of over 3000 kw. The views of the plant which we publish on the present page and page 16 will therefore be studied with some interest.

The boiler plant consists of three large water-tube boilers and one Lancashire boiler, from which steam at any desired pressure is supplied to the steam range. Practically the whole of one side of the test-house, as shown in Fig. 1, is occupied with a network of pipes arranged with suitable connecting-valves and flanges, so as to supply steam to any of the numerous test-beds; a separately-fired superheater is used, so that almost any desired degree of superheat can be obtained, while at the same time the degree of superheat is well under control. Below the steam-pipes and running the whole length of the test-house is a large-diameter exhaust-main communicating with two independent condensing plants. This condensing-main can be separated into two portions in order to allow separate trials on two independent plants to be carried out simultaneously, or, in the case of large-sized machines, both condensing plants can be used together to deal with the exhaust steam. The water from the circulating-pump is taken into large and carefully-calibrated tanks arranged in pairs, so that continuous measurements of the steam consumption of any plant can be made. Means are provided for checking the calibration of these tanks should inspecting engineers desire to do so.

Particular attention has been given to the problem of obtaining accurate measurements of the power developed. Standard instruments are used for this purpose, and these instruments are kept and used in a specially-constructed instrument-

cabin, all the power being led through this cabin and measured there. By this means the standard instruments are kept free from vibration, and since they are not moved about for coupling up to different machines and are frequently calibrated, their accuracy may be absolutely relied on.

In the case of alternating-current machines, the wave-form of every plant is observed and photographed under different conditions of loading, so that engineers can readily satisfy themselves before taking delivery of a plant that their requirements in this direction are being fully met.

Fig. 1, page 3, shows a turbo-alternator having a normal rated output of 6000 kw., erected and undergoing tests up to half load. In the background is the instrument-cabin referred to above, with the telegraph-board used for indicating the load on the machine undergoing test.

In testing turbo air-compressing plants, pumps, &c., the greatest possible care is taken to obtain accurate measurements of the quantity of air used. Fig. 3, on page 16, shows a double-ended turbo-blower on the test-bed. In this case the air is drawn from the test-house, and after being throttled to the required pressure, is discharged through a pipe to a large measuring-drum outside of the building. The measuring-drum is fitted with baffles, to steady up the flow of air and enable a reliable water-gauge reading to be taken immediately in front of the measuring-orifice. In most cases, however, the air is measured on the inlet side of the blower, as this largely reduces the number of corrections which have to be used in working out the results.

The turbo-geared plant, in which the gears are all cut on the special creeping-table patented by Messrs. Parsons, has recently attracted much notice, and particular attention has been devoted by the firm to the problem of obtaining thoroughly reliable tests on such machines. The methods already described for "testing turbo-dynamos" are used when they are applicable, but during the last few years the use of geared turbines for the direct driving of mills has called for the adoption of other methods.

The old mill-engine of the reciprocating type could be tested for its steam consumption per indicated horse-power after it had been erected on the site, and, provided it then realised the guaranteed figures and gave the requisite amount of power, the purchaser was expected to be content. It is needless to say, however, that this method gave no proof that the engine was economical as far as the power actually delivered to the shafting was concerned, although the method was probably the best that could be economically adopted in the case of reciprocating engines. Within recent years, however, when nearly all power extensions for mill-driving are taking the form of geared turbines, the matter has again had to be considered, and in view of the fact that the indicated horse-power of a turbine cannot be arrived at, Messrs. Parsons decided some time ago to instal such plant as would enable them to measure accurately the actual power delivered to the shafting.

Two powerful Heenan and Froude water-brakes have been installed, with which geared turbines can be tested up to loads of 2000 to 3000 brake horse-power, and one such geared turbine, complete with its rope-pulley, is shown in Fig. 2, page 16. The water-brake for testing can be seen at the right-hand side of the illustration.

The above description of the testing facilities afforded at Messrs. Parsons' works will be of special interest to engineers of plant for delivery abroad. Every effort is made at Heaton to discover any weak points, whether in the design or manufacture, of the machines manufactured, and, as a result, and as a reward of the necessarily high cost of carrying out these elaborate tests, they have been able to secure a very large proportion of the orders for British colonies and dependencies, and for other distant parts of the world.

WALLSEND SLIPWAY AND ENGINEERING WORKS.

FEW, if any, of the engineering factories in the North-East Coast district have made more rapid progress in recent years, alike in regard to the area of the shops and the importance of the work done, than those of the Wallsend Slipway and Engineering Company. The naval architects and engineers who attend the joint meeting next week will find much to interest them in the organisation

FIG. 4. GENERAL VIEW ON THE WORKS FROM THE RIVER TYNE.

and equipment of the establishment, and will further see very extensive developments, even although they may have been at the works two or three years ago, because large additions to the machine-shops have only now been completed. At the present moment, too, there is in course of construction a large amount of work of a varied and important nature. There are, for instance, the immense turbines of the battleship Malaya, the hull of which is being constructed at the new Armstrong yard at Walker; there is machinery for torpedo-boat destroyers, and a considerable amount of geared-turbine work. The progressive character of the management is further evidenced by the presence of a set of Diesel engines on the testing-bed, while in the mercantile department there are a number of reciprocating engines, of both the triple and quadruple-expansion type.

Reflection upon the progress of the works and upon the position it now occupies leads one to consider the influence of the size of works upon success in the management of such factories. Where the establishment is small, and the turnover not considerable, the burden of management must rest practically on one individual, and, especially if financial resource be lacking, there may be deficiency in the investigation of proposals for the advancement of business, either from the standpoint of design or of new *clientèle*. Again, when an establishment is of immense proportions, and the head cannot give direct personal attention to all that is going forward, there is a tendency to overlapping, and perhaps to inefficiency, even although the assistants are numerous, capable, and well-intentioned. On the other hand, with a moderate-sized factory having a large continuous turnover, justifying the appointment of a staff including men of sound practical knowledge, as well as designers of creative ability, the probabilities are that there is more enthusiasm, more admirably-directed effort, and greater cohesion. These results are in large measure produced by continuous contact between the chief and his staff, and particularly by the amount of direct personal supervision he can give to the work in progress and to all negotiations, either in connection with labour or the satisfying of clients. The Wallsend Slipway and Engineering Works belong to this third class, and it is widely recognised that the success of the works, both from the constructional and commercial point of view, is largely due to the influence of Mr. Andrew Laing, the managing director, who has under him a staff well organised and perhaps more numerous than is to be found in works of corresponding size. This is due to the volume of work done rather than to the size of the establishment. The number of men employed averages at the present time 2430, as compared with 1800 in 1904, when we last wrote upon the works, and with 1165 in 1896. The roofed-in area of the factory has advanced practically in the same proportion since 1896. Now it is 287,927 sq. ft., as compared with 198,430 sq. ft. in 1904, and 132,590 sq. ft. in 1896. But the volume and value of the work done has enormously increased. This is due to improved mechanical equipment as well as to the type of work undertaken. The average production of new propelling machinery in the ten years ending 1896 was 26,145 horse-power. In the next ten years, however, this average had increased to 59,198 horse-power, whereas for the past seven years the average is 83,096 horse-power. On Table I. there is given a return of the output in each year since 1887. It is a striking fact that whereas in the first twenty years of the company's history the output was 432,273 horse-power, it has been 1,077,685 horse-power during the past fifteen years. Up to 1896 the largest engines made were of 4500 horse-power, since then sets of engines of 70,000 to 80,000 horse-power have been completed.

TABLE I.—*Return of Horse-Power Produced Each Year Since* 1887.

Year.	Total I.H.P. for Year.	Average I.H.P. for Each Set of Engines.	Maximum I.H.P. of Any One Set.
1887	17,750	1,200	2,925
1888	23,250	1,100	2,150
1889	39,750	1,420	2,260
1890	40,170	1,550	3,360
1891	34,220	1,500	3,300
1892	25,700	1,350	4,500
1893	16,640	1,850	3,000
1894	21,250	1,125	2,500
1895	29,260	1,725	3,000
1896	13,460	1,350	2,800
1897	22,675	1,625	5,000
1898	68,100	4,000	11,500
1899	67,600	3,400	12,000
1900	51,750	2,200	5,000
1901	46,650	2,350	4,500
1902	69,150	3,850	12,500
1903	42,360	2,500	6,600
1904	41,400	2,600	6,000
1905	66,800	3,200	23,000
1906	115,500	8,250	70,000
1907	70,100	5,390	23,500
1908	33,175	2,015	8,000
1909	55,800	4,295	22,000
1910	67,250	11,210	27,000
1911	72,800	4,550	14,500
1912	123,000	6,835	24,500
1913	159,550	9,385	66,000

The works were originally organised in 1871, primarily as a ship-repairing establishment, with slipways and repair-shops. The manufacture of new propelling engines for ships was commenced in 1874, when Mr. William Boyd became managing director. The company gradually won confidence, and from the outset did good work towards increasing the economy of the propelling machinery of the cargo and intermediate classes of ships. A new era opened in 1897, when Mr. Andrew Laing, formerly of the Fairfield Company, took over the management of the works. Soon afterwards the British Admiralty entrusted the company with orders for the construction of machinery for practically all types of warships built either at the Royal Dockyards or in private shipbuilding works. Most notable of the warships engined are the battleships Superb, Orion, Queen Elizabeth, and the Malaya, and of armoured cruisers the most notable is the Warrior, while a large number of torpedo-boat destroyers have also had their machinery from the Wallsend Works.

As regards the equipment of the works, perhaps the most eloquent testimony is the fact that the largest set of turbine-engines yet completed for a

British warship was despatched from the Wallsend Works within eleven months from the placing of the contract. In referring to the equipment, we propose to devote special attention to the extensions which have just been completed. In Figs. 1 and 2, on page 4, there are shown, drawn to the same scale, two key plans of the works, the former showing the size and arrangement of the works in 1896, and the latter at the present time. It will be seen that the slip-ways have been dispensed with. The Willington Gut is confined largely to ships undergoing repair, and a new jetty along the entire river frontage has been built for new ships. Instead of the old 80-ton sheerlegs there has been erected on the river side jetty a hammer-head electric crane which lifts 180 tons. The old engine-fitting shop was 279 ft. 6 in. long and 71 ft. 6 in. span, but alongside, occupying the site of the old brass foundry, coppersmiths' shop, and blacksmiths' shop, there has been erected a very fine and well-lighted shop by Sir W. Arrol and Co. This has from time to time been lengthened; the last extension, only recently carried out, being 90 ft., so that the shop now is 570 ft. long. In continuation of the old fitting-shop there has been erected a new machine-shop, which is only now completed, having a length of 390 ft. and a span of 69 ft. 9 in. No doubt the old fitting-shop will ultimately be reconstructed, so that the new machine-shop will then be 669 ft. in length. Alongside is now a shop for small machines; it is 450 ft. long. These new shops are seen in the distance to the right of the general view of the works taken from the river, Fig. 4, page 5, and the boiler works are immediately behind the hammer-head crane.

Interior views of the new engine-shops are given in Figs. 5 to 8, on Plates I. and II. In these shops is a collection of machines of various types for dealing with the largest turbines that are ever likely to be designed. Among the new tools in the machine-shop is a Barrow's patent turbine-boring machine, by Messrs. Shanks, of Johnstone. It has a traverse of 6 ft., including boring-stays, and the base-plate is 36 ft. long by 13 ft. wide. This is in addition to a machine fitted earlier for boring the casings and forming the grooves in them. This was a circular planing-machine by Messrs. Armstrong, Whitworth and Co., having a table 20 ft. in diameter, with an available height for work of 13 ft. For rotor-turning work there is a new Armstrong-Whitworth 60-in. lathe, having a bed 66 ft. 3 in. long, in addition to the large lathe which was installed by the same firm in 1904, and was then illustrated in ENGINEERING. The older tool takes work 18 ft. in diameter and 50 ft. long. Messrs. Armstrong, Whitworth and Co. have also delivered quite recently a 6 ft. planing-machine driven by a 30-horse-power motor, and another planing-machine to take work 4 ft. 6 in. by 4 ft. 6 in. high and 13 ft. long. Messrs. G. and A. Harvey have fitted a facing-lathe for turning, boring, and surfacing, the face-plate being suited for work 8 ft. in diameter, and a 4-ft. horizontal boring and facing machine. Another notable recent addition is a Shanks vertical and horizontal planing-machine, with a revolving table 7 ft. by 5 ft. For the erection and testing of turbines there has been fitted in the new shops a very well laid bed, to supersede the old wooden blocks formerly used. The new bed consists of twenty-three cast-iron girders, of a collective weight of 55 tons, and ensures an absolutely true surface.

The latest addition to the machine-shop is illustrated in Fig. 5, Plate I. This shop is 390 ft. long and 69 ft. 9 in. span. To the right in the view there will be seen one of the large turbine-lathes, while beyond there is a turbine-rotor on the balancing-bed, and still further in the distance the first of the Diesel engines made by the firm. The small machine-shop is situated parallel with and to the left of this view, and of this bay a view is given in Fig. 6. It is 451 ft. long and of 30 ft. 9 in. span. The character of the work done is indicated by the collection of parts shown in the view. The new erecting-shop is illustrated by Figs. 7 and 8, Plate II. This shop is 570 ft. long and of 55 ft. span. To the left of Fig. 7 there is seen part of one of the large turbine-lathes—that with 6-ft. centres and 66-ft. 3-in. bed. Beyond is a series of horizontal and radial boring-machines, while to the right, in the foreground, is a vertical and horizontal planer working on a sole-plate, and beyond it three turbine-casing boring-mills. In the distance will be seen turbines in various stages of construction. These are better seen in Fig. 8. The turbine on the left of this view is being water-tested, and on the right there will be seen a portion of a turbine gear-case in the boring-mill. The overhead cranes in these new shops are all of 75-ton lifting power, the newer ones being by Messrs. Armstrong, Whitworth and Co.

The boiler-shop has also been extended. Twenty years ago the average number of boilers made was 30 per annum; now the number is 77. The boiler-shop is in two sections, one 328 ft. long and 70 ft. span, for the erection work, and the other, 257 ft. 6 in. long, in three spans, respectively 31 ft. 6 in., 47 ft. 9 in., and 28 ft. 3 in., for machine work. Parallel with the latter is the light plate-work shed; uptakes, funnels, &c., are assembled in the yard adjoining this shed. As to the equipment, it may be said that the plate-edge planer takes plates 35 ft. long, the vertical plate-bending rolls deal with plates 12 ft. 6 in. wide, and the hydraulic riveting-machine has a gap of 12 ft. Over this latter there has just been erected a Royce electric-crane of 60 tons lifting power; another addition is a 6-in. spindle high-speed drilling-machine, by Buckton, for nickel steel plates. In connection with the hydraulic machine-tools there have been laid down recently by Arrol two sets of three-throw electrically-driven hydraulic pumps, each set being capable of delivering 60 gallons per minute at a working pressure of 1500 lb. per sq. in. There is also a new accumulator, with a ram 14 in. in diameter, adapted for a 16-ft. stroke. There has also been added a two-stage, two-crank air-compressor by Belliss and Morcom. At the end of the boiler-shop there has been built an annexe to accommodate the plant for electro-zincing boiler-tubes, including a three-phase motor and special dynamo by Messrs. Clarke, Chapman and Co.

The iron foundry is 198 ft. 6 in. long, and deals with castings up to 30 tons, while in the brass foundry and coppersmithy the two bays have been extended 60 ft., and additional machine-tools fitted. Another recent improvement is the new general store—a two-storey building, 93 ft. long, 77 ft. 6 in. wide, and 28 ft. 10½ in. high. It is specially heated, and the racks are commanded by a Royce electric jib-crane. A new electric fire-pump has been added.

An interesting feature is that, although the works are entirely run by electric current from the public supply works, the recently-built shops are lighted by high-pressure gas; the old burner-bracket, it is held, confers advantages in the illumination temporarily of the dark recesses of machines or jobs, while the general lighting is said to be steadier than with the electric arc-lamps.

The jetties built along the river front on each side of the graving-dock take ships 700 ft. or 800 ft. long, while the 180-ton hammer-head crane, built by Arrol, has sufficient outreach to command two ships of fairly wide beam. To facilitate the berthing of ships there are three sets of mooring buoys in the river, as shown in the plan. The railway lines to the jetties pass through all the shops, so that the transport of material to the ships is a simple matter. With its graving-dock to take ships 540 ft. long, and the berthage in the Willington Gut, the works are well supplied with accommodation for ships fitting out or being repaired, while the improvements in the plan of the works and in their equipment, to which we have referred, show that a progresive policy is being pursued as vigorously now as during the past fifteen years.

THE NEW JOINT DOCK AT HULL.

(*Concluded from page 867, vol. xcvii.*)

CONTINUING our description of the equipment of the new dock, we may now say something of the pumping machinery for the graving-docks, which was supplied by Messrs. W. H. Allen, Son and Co., Limited, of Bedford. It will be remembered that the installation is electrically driven from a 440-volt direct-current dock system. It consists of two main centrifugal pumps and motors with switch-gear, a drainage-pump and charging-pump, with motors and switch-gear, and, of course, the necessary pipe-work and valves. Messrs. Allen supplied the whole equipment. It is contained in a chamber formed in the wall between the two graving-docks, and is well shown in Fig. 76, on page 8, which is a view inside the chamber. The lay-out is shown in greater detail in Figs. 72 to 74, on page 7. The main pumps are of the "Conqueror" centrifugal type and have suction and discharge branches, 42 in. in diameter. Each pump discharges a mean quantity of 36,000 gallons of water per minute against a head of 40 ft. The pumps run at a speed of 375 to 416 revolutions per minute, and each absorbs a maximum horse-power of 390. The casings and discs are of cast iron, and the spindles are of steel. The spindles run in ring-lubricated bearings, arranged entirely outside the casings. One of the pumps is illustrated separately in Fig. 75.

Each pump is driven by a 420-brake-horse-power open-type motor, fitted with shields to prevent water dripping on the windings. This is well shown in the foreground of Fig. 76. The starting-gear for each motor consists of an ironclad pillar containing a multiple-lever starter, formed of a series of edgewise-type switches. Step-by-step operation by means of a slow-motion ratchet-type handle is fitted. This handle actuates a double-pole magnetic blow-out circuit-breaker which interlocks with the starter, so that the breaker can only be put on when the starter is off, and so that the breaker is tripped and cannot be put on again until the starter is returned to the off position in the event of the attendant failing to complete the operation of starting. One of the pillars can be seen to the right-hand side of Fig. 76.

The lay-out of the pipe-work is clearly shown in Figs. 72 to 74. The suction and discharge-pipes of each pump are of cast iron, and are 42 in. in diameter. They merge into a main discharge 60 in. in diameter. Hydraulically-operated sluice-valves are fitted on the suction and discharge sides of the pumps, and so arranged that each pump may draw water from either dock as required. This will be quite clear from the figures. The sluice-valves are 42 in. in diameter, and are arranged to work from the 750 lb. per sq. in. pressure mains which feed the dock-gate operating machinery. They are provided with controlling-valves. A retaining-valve of the multi-flap type with cast-iron casing is fitted on the discharge side of each main pump. The drainage pump has suction and discharge-pipes, 14 in. in diameter, and delivers 3000 gallons of water per minute against a total suction and delivery head of 54 ft. The discharge is carried to one of the 42-in. discharges of the main pumps, as is shown in Fig. 74. The pump-casing is of cast iron, the disc of gun-metal, and the spindle of manganese bronze. The speed of the pump is 1100 revolutions per minute, and it is driven by a semi-enclosed motor of 75 brake horse-power. The charging-pump, which can be seen in the lower right-hand corner of Fig. 74, is of the two-throw single-acting type, with barrels 8 in. in diameter by 5 in. stroke. It is capable of charging the main and drainage pumps and pipe-work in a few minutes. It is driven by a semi-enclosed motor at 750 revolutions per minute. Air-vent pipes have been provided to free the suction culvert from air, and water-level indicators are fitted showing the level of water in the graving docks and outside. One of them can be seen in Fig. 76.

The only features of the equipment of the dock with which we have still to deal are the coal-handling arrangements and the warehouse and quay cranes. We have already referred briefly to the coal-handling plant. It is fixed on the north sides of the main basin and of the north-east arm, and consists of two electrically-driven belt-conveyors and two hydraulic coal-tips. The number of conveyors will ultimately be extended to five. Each has a capacity of 800 tons an hour. The arrangement in each case consists of a tipping-bin situated under a railway siding lying on a gradient. Above the bin there is a tipping-door, and on each side of it a tipping-table lying in the line of the track. Two loaded wagons will be dealt with at a time, and will be run down the gradient under the control of their hand-brakes. On arriving over the bin their contents will be tipped through their bottom doors, if these are fitted, through a hatch into the bin. If end-tipping wagons are in use, they will be up-ended by the tipping-tables, and will discharge through the same hatch. The wagons will then pass on down the gradient, and a second pair will come into position. At the bottom of the bin there is a steel-belt conveyor, which will carry the coal to the quay side, and discharge it through a chute to the ship. The conveyor is carried in a lattice-work girder framework on steel towers, and gradually lifts the coal from the level of the bin below the sidings to a height convenient for discharging to a ship's hold. The quay-side tower carrying the last section of girder framework is fitted with operating gear for altering the level

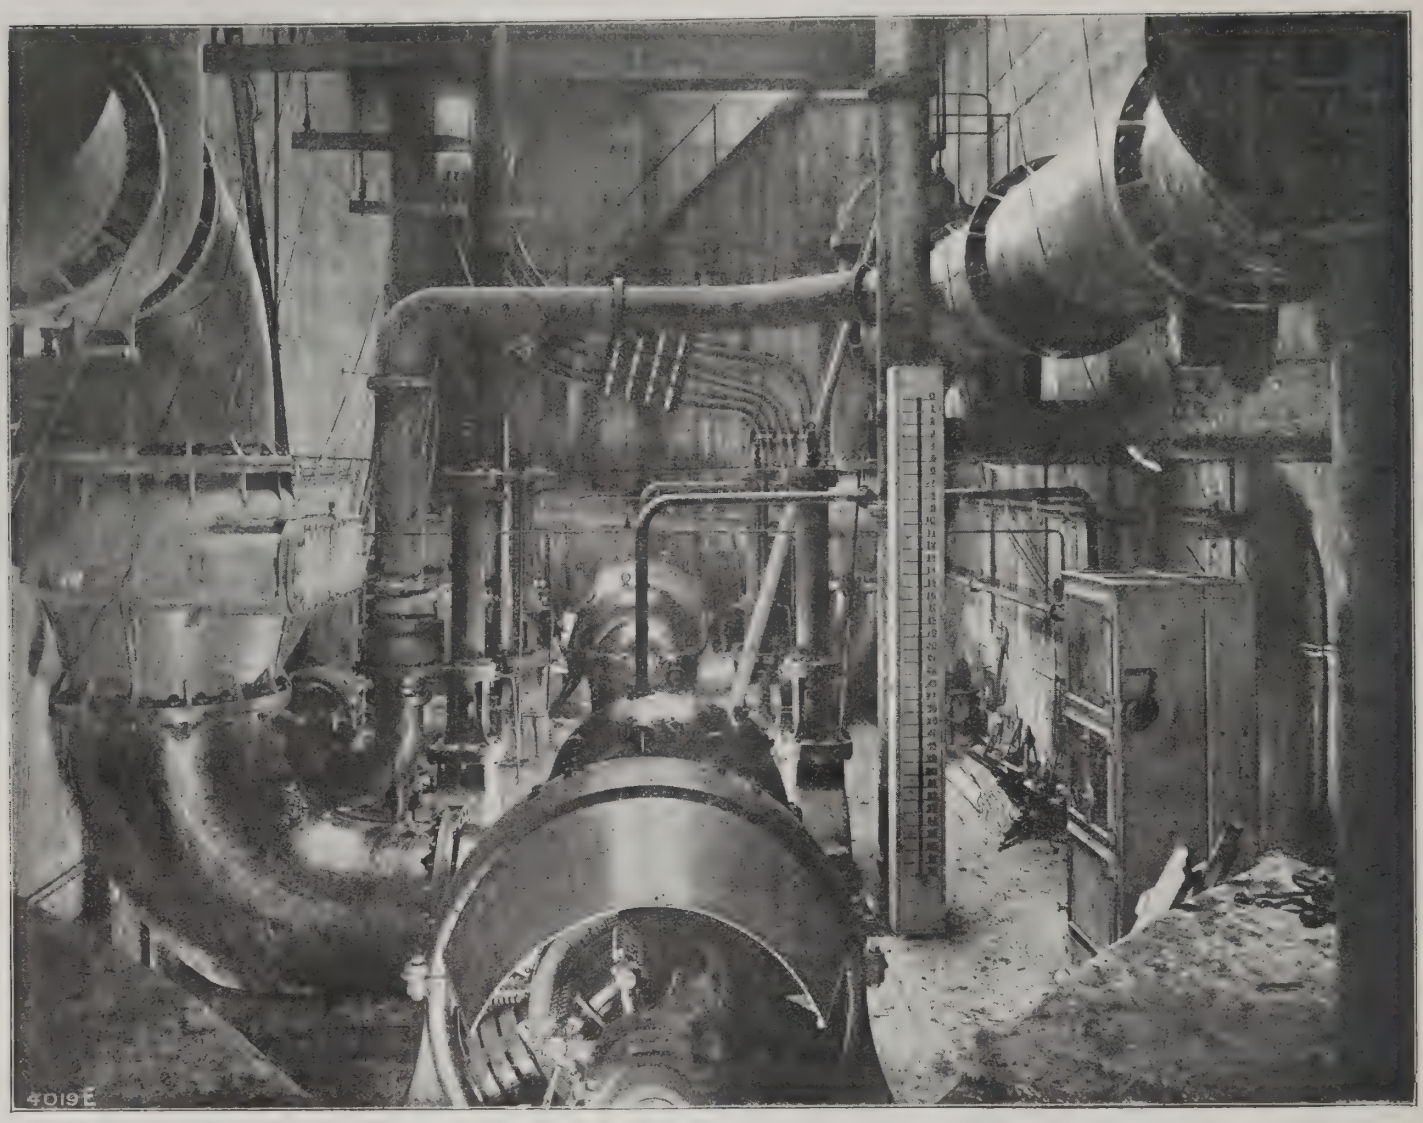

FIG. 76. PUMPING PLANT FOR GRAVING-DOCKS; MESSRS. W. H. ALLEN, SON AND CO., LIMITED, BEDFORD.

of discharge and controlling the position of the chute. The maximum height of delivery from high water of ordinary spring tides is 66 ft. at 28 ft. out. The adjustment in the length of the chute is 13 ft., and it is capable of a lateral movement over 20 deg. The conveyors were supplied by Messrs. Head, Wrightson and Co., Limited, of Thornaby-on-Tees.

The other part of the coal-handling plant consists of two hydraulic coal-hoists, built by Messrs. Sir W. G. Armstrong, Whitworth and Co., Ltd., of Newcastle-on-Tyne. One of them is fixed and the other is movable along the quay side, so that the hoists can be used for loading either one or two ships. Each hoist has a capacity of 500 tons an hour. A view of the hoists during erection is given in Fig. 82, on page 9, while general arrangement drawings of the movable type are given in Figs. 77 to 80, on Plate III., and a drawing of the upper part of the fixed coal-hoist is given in Fig. 81. The hoists are each double-powered and are arranged to deal with wagons of a gross weight of either 25 or 35 tons. The maximum lift from quay-level for the fixed hoist is 72 ft., and the maximum height of delivery from high water of ordinary spring tides 55 ft. The maximum lift from quay-level for the movable hoist is 57 ft. In each case the maximum distance of delivery out from the quay is 28 ft., the adjustment in the length of the chute 13 ft., and the lateral movement of the chute 20 deg.

The constructional features of the moving hoist will be followed from the figures on Plate III. The fixed hoist is generally the same both in lay-out and details, except that it is rather higher, and that holding-down bolts embedded in the concrete take the place of the travelling bogies. We will refer for the remainder of our description to the travelling-hoist shown in the figures. As will be seen, the framework is of steel plates and sections. It is constructed with a free central space, in which the cradle travels in guides. The cradle itself is in essence a platform built up of joists, and having an inverted V frame at each side. These frames carry a cross-bar at their outer end, to which the lifting-ropes are attached. The cradle carries a pair of rails for the wagon being lifted, the rails being turned up at their outer end to form a stop when the cradle is tilted for tipping. The wagon being dealt with is secured to the cradle by chains. Underneath the cradle there is a hopper for dealing with hopper-wagons, an automatic tumbling-apron being fitted to bridge over the space between the lower edge of the hopper and the heel end of the main chute.

The cradle is lifted by three hydraulic rams fixed vertically on one side of the framework. They can best be seen at the left-hand side of Fig. 78. The object in fitting three rams is to save water when less than the maximum load is being dealt with, as in this case all the cylinders need not be used. The main lifting ropes are 7½ in. in circumference. As is well shown in the figures, they are taken over a pair of large sheaves carried at the top of the framework, and are secured to the centre of the top cross-beam of the cage. Multiplying sheaves are fitted for the lifting ropes, the ratio being 2 to 1. One of the lifting cylinders is arranged to be in constant communication with the accumulator. This cylinder balances the weight, the other cylinders supplying the extra power necessary for lifting. The speed of lifting is 180 ft. a minute. The hydraulic cylinder, for tipping the cradle, is placed over the lifting cylinders. It is fitted with 2 to 1 multiplying gear, and operates through a steel rope 4¾ in. in circumference. The arrangement of the lifting and tipping ropes allows the cradle to be tipped at any part of its vertical travel.

The chute is of steel plate and angles, and is fitted with anti-breaking doors at its front end, by which the flow of coal can be regulated. The chute is raised or lowered by temporarily attaching it to the cradle by hinged pawls. Its outer end is raised or lowered, to suit the conditions of working, by means of a wire-rope, 3½ in. in circumference, which is connected to an hydraulic cylinder fixed on the back of the hoist framework. The arrangement is clearly indicated in Fig. 77. Multiplying gear, having a ratio 8 to 1, is fitted to the ram. A lengthening piece, 6 ft. long, is fitted to the chute, its position being controlled by hand-gear. Pressure-water supply to the hoist is obtained through stand-pipes, which are shown in Fig. 78. Connection can be made at various points on the dock-quay.

A very complete arrangement of gantries and sidings has been laid down for the handling of the coal-wagons to and from the hoist. The loaded wagons come along the quay-side and mount a traverser which lifts them the few inches necessary to the level of the cradle platform when in its bottom position. The traverser has to be set only once to suit the position of the hoist, and is not moved as each wagon comes on to it. The traverser has a turntable at its far end, opposite the hoist, and wagons run along it to this table, are turned through 90 deg., and run on to the cradle. They are lifted and tipped, and then lowered to the level of a gantry carrying a second traverser with a turntable. This is partly shown in Fig. 77. The wagons run off on to the turntable, are turned through 90 deg., and move along the gantry to a dead end. Here they reverse their direction, and coming back run on to a branch gantry, which

carries them away to the marshalling sidings. A somewhat similar arrangement is used for the fixed hoist, but the gantry carries no turntable, and the wagons run straight away from the hoist and the siding. The whole lay-out is very ingenious, and should prove very convenient and speedy in practice.

Concluding our description of the dock with some reference to the crane equipment, we may say that present plans allow for the fitting of nine 10-ton, four 7-ton, thirty 3-ton, and nine 1½-ton electric cranes, and one 80-ton floating-crane. The floating-crane, which is intended for general service in the dock, is being built by Messrs. Werf Gusto (A. F. Smulders, of Schiedam, Holland). Of the electric cranes, twenty-five are at present being supplied by Messrs. Royce, Limited, of Trafford Park, Manchester, and fifteen by Messrs. Craven Brothers, of Vauxhall Works, Reddish, Stockport. The electric cranes are distributed over four quays and on the roofs of the warehouses which line two sides of the north-west arm. All are of the travelling type, and the arrangement allows of one 10-ton and three 3-ton cranes working cargo to or from the same ship. The roof-cranes handle cargo from the wharf-cranes, and lift it over the warehouses on the far side, or from the warehouses themselves through the hatches in the flat roof. An idea of the crane distribution is given by Fig. 82, annexed, which shows the south quay of the north-west arm. It should be understood, however, that the crane equipment shown in this figure is not complete, and that the wharf-cranes will be distributed along the whole length of the quay.

The general design of the twenty-five 3-ton cranes, supplied by Messrs. Royce, is illustrated in Fig. 84, on page 10. They are fitted with Musker-Davidson luffing-gear. The maximum radius of the jib is 50 ft., and the minimum 20 ft.; the luffing speed is 150 ft. per minute; the hoisting speed with 3 tons is 150 ft. per minute, and with 1½ tons 250 ft. per minute. The slewing speed is 400 ft. per minute, and the travelling speed 30 ft. per minute. The height from the crane-rails to the point of the jib at maximum radius is 80 ft. The travelling-rails are at 15 ft. centres, and the wheel base of each

crane is 19 ft. The motors, which are of the totally-enclosed type with 6-hour rating, operate from the 440-volt direct-current supply. The hoisting motor is 45 horse-power, the slewing 5 brake horse-power, and the luffing and travelling each 8 brake horse-power. Tramway-type controllers are fitted. Current is conveyed to the cranes through armoured cable from plug-boxes fixed at intervals along the quay, and each crane is provided for this purpose with a revolving cable drum on one of the bottom carriages.

Each crane is supported on four cast-steel travelling-wheels with single flanges on the inside. The travelling motion is fitted with hand-gear. Automatic electrical safeguards against overrunning in either direction are provided for the hoisting and luffing motions. All the toothed gear on the cranes are of machine-cut cast steel, except the motor pinions, which are of raw hide. Each motion is fitted with an electric brake, and in the case of the hoisting motion a foot-brake is also provided on the barrel shaft, for quick lowering without current. In such circumstances the electric brake is held off by a hand release attachment. The gear for hoisting, slewing, and luffing is carried on a central revolving mast which is pivoted and supported at the foot in a cast-steel bearing, and at about the centre of its length by a roller-path. The jib is carried at the top end of the mast by a heavy fixed shaft, and is balanced by cast-iron weights fixed at the tail end of the jib structure. The special advantage of the luffing arrangements is that the load during luffing is not lifted, as in the ordinary jib-crane, but moves in a horizontal line. As a consequence there is considerable saving in power, and a small luffing motor only is required. In addition quick luffing is permissible. We have described the Musker-Davidson gear in detail in the past. The cranes were tested for stability by hanging a load of 6 tons on the hook at the extreme radius in any position of the jib. No jacks or rail-clips were used, and there was no indication of the slightest lift in the structure or the wheels.

Of the cranes supplied by Messrs. Craven Brothers, nine are of 10 tons capacity, and were, in general, of somewhat the same type as those of Messrs. Royce, just described. Five are situated on the south quay and four on the north quay of the north-west arm. They are fitted with Musker-Davidson luffing-gear. Two of the cranes on the north quay and all the five on the south are fitted with telescopic grain-elevators, which are carried by supplementary jibs at the back of the centre vertical post. When not in use the elevator-jibs are derricked to the "in" position, raising the elevators and stowing them alongside the central mast. The cranes are then ready for the ordinary work of cargo-handling. Similarly, when the elevators are put into action the main jib is derricked up to the "in" position. The elevators were manufactured by Messrs. Henry Simon, Limited, of Manchester, and are each capable of discharging 120 tons of bulk grain per hour. They are driven by separate motors and discharge grain down chutes alongside the gantry into the grain subways that we dealt with in our previous article. The speeds of movement of the 10-ton cranes are as follow:—Hoisting 10 tons, 50 ft. per minute; hoisting 3 tons, 150 ft. per minute; luffing speed with full load, 100 ft. per minute; slewing speed with hook at maximum radius at full load, 300 ft. per minute; travelling speed without load, 30 ft. per minute.

Of the 1½-ton roof cranes, three are placed on the roof of the two-storey warehouses of the south quay, and three on the roof of the single-storied warehouse on the north quay. The former cranes have a maximum radius of 47 ft. 10½ in., and the latter a radius of 57 ft. 10½ in. Some of the cranes in position on the south quay can be seen in Fig. 83. The cranes are carried on tracks along the outer edge of the warehouses, the rail centres being 20 ft. 7½ in. The cranes have hoisting, slewing, luffing and travelling motions of the following maximum speeds:—Hoisting with full load, 250 ft. per minute; luffing with full load, 200 ft. per minute; slewing with hook at maximum radius at full load, 450 ft. per minute; travelling without load, 50 ft. per minute. The cranes luff in to a minimum radius of 20 ft. and 25 ft. respectively, and the luffing motion is worked on Messrs. Craven's patent system, by means of which the load is traversed in or out in a horizontal line while luffing. This feature is obtained solely by a beam pivoted at the jib-head, and carrying the jib-sheave at its lower end. A radius rope attached to its upper end is anchored to an A-frame fixed on the revolving superstructure. The sheave is constrained to move in a parabolic path, having a certain relationship to the position of the barrel, which makes the sum of the distances from the barrel to the sheave and from the sheave to the snatch-block, constant throughout the range of derricking. The cranes are of the plated gantry ported type mounted on four travelling wheels, the revolving superstructure being carried on a pivoted centre-post resting at the bottom on a compensating foot-step bearing and guided by back and front rollers inside a vertical roller-path at the top of the gantry. The roller-path also forms a pin-rack for the slewing motion.

THE NEW JOINT DOCK AT HULL.

FIG. 84. 3-TON ELECTRIC JIB-CRANE; MESSRS. ROYCE, LIMITED, MANCHESTER.

THE ENGINEERING DEPARTMENTS AT ARMSTRONG COLLEGE, NEWCASTLE-ON-TYNE.

AN important addition has been made to the already highly satisfactory equipment of Armstrong College in the University of Durham, in the form of an hydraulic laboratory, which has been built parallel to the existing mechanical laboratory. This addition makes more interesting the fact that the inaugural meeting of next week's conference of naval architects will be held in the King's Hall at the College, and that the laboratories will be open for inspection throughout the meetings. Armstrong College is one of the most successful and serviceable of the colleges of science which have grown up in recent years in the provinces, because it brings conveniences for pursuing a study of theoretical work within the reach of those trained on the practical side in the various factories on the North-East Coast. Time was when if, say, a draughtsman was wanted for any of the shipbuilding or marine engineering establishments on the Tyne and Wear, employers had to look to the Clyde and older districts. But, largely as a consequence of the work done at Armstrong College, it is now possible to find in the district men thoroughly capable not only of continuing the traditions of the North-East Coast establishments, but of assisting the advance in recent years towards the improvement in the class of work done.

Armstrong College is, perhaps, wider in its scope than some of the other corresponding institutions in the provinces, as it embraces in its purview every department of the arts and sciences, and fulfils also the function of a normal college for the training of teachers for primary and secondary schools. Degrees are given in practically every department of mental activity. In connection with the agricultural department, much useful advisory work is done in agricultural chemistry, agricultural botany, zoology and forestry, and a live-stock officer gives practical advice throughout the four northern counties. Last year, too, a most promising faculty of commerce was organised, so that it will be seen that Principal W. H. Hadow fully realises the possibilities of the College in its relation to the industries of the district. We are here, however, concerned primarily with the applied science work, and especially the engineering and

naval architecture departments; but one or two facts regarding the general progress of the College may be indicated. It should be understood at the outset that the College is almost entirely for day students, the view taken being that the evening classes in the secondary schools, not only in Newcastle, but in other towns in the district, afford sufficient facility for those who are able only to attend evening classes. Special arrangements were made in 1909 whereby the Rutherford Technical College took over the greater part of the evening work carried on up to that time at Armstrong College, but special courses are arranged, consisting of a series of lectures in the evenings in the engineering and other departments. Thus there has been given a course on the application of the steam-turbine for marine propulsion; another on the results obtained from trials in connection with the experimental machinery in the mechanical laboratory of the College; yet another dealt with hydraulics for civil engineers or others. In other sections there are similar lectures, as, for instance, on applied chemistry, carbonisation of coal, metallography, the utilisation of fuel, and some applications of the electrical furnace.

These series of lectures, which are arranged independently of the ordinary curriculum, have proved most satisfactory, being open to anyone on payment of a purely nominal fee. Another feature of the College is the number of prizes and scholarships which the munificence of those resident in the district has made available for students in the College; while, either as governors or in some other capacity, the employers of labour in the district have shown a keen and helpful interest in advancing the institution. That this help and interest are welcomed is evidenced by the fact that in ten years the number of day students has increased from 503 to 722, while the number of the staff has been augmented from 55 to 90.

The College was founded in 1871 by the combined efforts of the University of Durham and the North of England Institute of Mining and Mechanical Engineers. It was originally intended, as its name—the Durham University College of Physical Science—implies, as a purely scientific institution, but ultimately increasing recognition was afforded by it to the literary side. In 1904 a new wing was opened, in memory of the late Lord Armstrong, and, in his honour, the College then received the title it has since borne. In 1909 the new University of Durham Act, in reconstituting the University, materially altered the status of the College, to which it gave full representation on the new Senate and admission to university degrees in arts as well as in science; admission to degrees in science has been given to the College since its foundation. A view of the College as it is to-day is given in Fig. 1, on Plate IV.

Applied Science embraces the following sections:—Mechanical Engineering (this is the basis of all branches of Applied Science); Marine Engineering, including ship propulsion; Civil Engineering; Electrical Engineering; Naval Architecture; Mining (coal and metal); and Metallurgy. In any one of these sections the Degree of B.Sc. is obtainable after a three years' course of study in certain specified subjects, the list and scope of which in each section has been drawn up by the advice and aid of experts in the several professions concerned. The above refers to the ordinary Pass Degree. An Honours Degree is available in the case of those who can spend a minimum of an additional year at college in the study of more specialised and advanced branches of the subject of the Degree. The M.Sc. and the D.Sc. are both obtainable in the usual way after the lapse of some years of practice and on the presentation of a thesis of sufficiently high standard.

In each section embraced in the Applied Science Section laboratory work is a feature of the course of instruction, and in the laboratories research work is continually being prosecuted. For example, in the Mechanical Engineering Laboratory many series of elaborate and exhaustive experiments have been carried out on machinery of commercial dimensions, on the following previously undetermined points in the economical use of steam in the production of power:—Influence on economy of variation in the cylinder ratios of stage-expansion engines; influence of variation in the degree of expansion in each individual cylinder, and of variation in the total degree of expansion from the first to the last cylinder; influence of degree of vacuum in itself, and the determination of the maximum-economy vacuum in given conditions; surface condensation generally, and the design of surface-condensers and air-pumps from the point of view of maximum economic effect; reciprocating *versus* rotary air-pumps; effect upon economy of degree of boiler pressure; effects of superheating the working steam; re-heating of the steam as it passes through the receivers of stage-expansion engines; relative effects of throttling *versus* automatic-expansion governors; economic effect of different crank-angles in four-cylinder quadruple-expansion engines; and effects due to variation in piston speeds carried to extreme limits. The above is a summary of the principal experiments which have so far been made upon the experimental engines and boiler. Many minor tests of diverse kinds have, in addition, been carried out. There have also been tests on the economy of internal-combustion engines and gas-producing plants.

All research work is, when possible, carried to the point where definite and useful results are arrived at, and in many cases these results have been embodied in papers, which have been read before technical institutions. In the Electrical Engineering Laboratory also a great deal of research work has been undertaken, and in both laboratories this work is still actively prosecuted. As far as is consistent with due attention to their other work in college, third and fourth-year students are required to take part in research work, both in respect of the making of the actual experiments and in reducing, arranging, and analysing and co-ordinating the figures obtained by observation.

A special feature in the applied science training is the close touch maintained between the engineering departments of the college and the industrial workshops of the district. The Professor of Engineering has a standing demand from the industrial establishments of the North of England for students who have done themselves credit in their college course, and who have either earned distinction or taken honours in their final year. Such young men are keenly competed for and are engaged at once to complete their training on the practical side in the best establishments, and are, moreover, generally accorded a "living wage" from the very commencement of their pupilage, which is often a very material consideration. It is an encouraging feature of the present day in this country that young men who have been trained at college in technical theory, judiciously combined with a certain amount of such practice as a laboratory can afford, are undoubtedly in growing demand. The professor finds that all those who have been painstaking in their college career ultimately find posts in the industrial world which suit them, many speedily attaining to positions of trust and responsibility.

Turning now specially to the engineering section, it may be premised that the department of engineering and naval architecture was instituted in 1891, both being then combined. The employers in the district at that time subscribed the funds to establish a Chair, and nominated as professor Mr. (now Dr.) R. L. Weighton, who had ten years previously come from the Clyde to be chief draughtsman with Messrs. Hawthorn, Leslie and Co. From that time forward continuous success has characterised the work of the department, and there has passed from the engineering department a steady flow of men capable of taking an active part in the practical work of the district. This is evidenced by the number of entries in the department of engineering each year since the beginning of the department, as given in Table I. Up to 1906 there is included in the list students in naval architecture, as up to that time Professor Weighton was himself responsible for naval architecture. In that year it was considered that the number of students coming forward for naval architecture justified the institution of a Chair, which is now occupied by Professor J. J. Welch, formerly of the Royal Corps of Naval Constructors at the Admiralty. The falling off in evening students is accounted for by the discontinuance of the ordinary evening classes and the arrangements made with Rutherford Technical College to take over this work. The evening students from that date attended the special series of lectures arranged from time to time within the university. The growth of the department must therefore be judged by the steadily increasing number of entries for the day classes. It should be made clear that each student entered for day-work attends on an average two-and-a-half classes; so that if the total of entries in column 1 of the table is divided by this, the number of students may be ascertained with a fair degree of accuracy. Thus, at the present time, there are 201 students in engineering alone. This, again, is exclusive of large classes held on Saturday afternoons for colliery engineers and foremen miners, and these classes, again, are attended by about 100 students. It is further interesting to note the classification of the students. Table II. gives a list of the numbers attending the various day schools. This, of course, does not include evening students nor Saturday students. It may be mentioned that during the past year the total number of day students was 201, whereas in the first year of the department the corresponding number was twelve. In addition to the classes indicated in Table II., the students, of course, are required to attend classes in mathematics, physics, chemistry, and so on.

TABLE I.—*Entries in the Department of Engineering since the Beginning of the Department.*

Year.	Day.	Evening.	Total.	Remarks.
1891-2	37	198	235	
1892-3	43	183	226	
1893-4	59	190	249	
1894-5	112	191	303	
1895-6	132	194	326	
1896-7	142	284	426	
1897-8	113	266	379	
1898-9	144	286	430	
1899-0	155	283	438	
1900-1	156	306	462	
1901-2	204	281	485	
1902-3	195	300	495	
1903-4	214	269	483	
1904-5	342	253	595	
1905-6	312	272	584	
1906-7	279	258	537	Naval architects not included; separate department instituted.
1907-8	270	196	466	
1908-9	323	209	532	
1909-10	378	87	465	Arrangement made with Rutherford Technical College by which most evening work was transferred to it.
1910-11	408	42	450	
1911-12	428	49	477	
1912-13	454	65	519	
1913-14	498	30	528	

TABLE II.—*List of Students in the various Day Classes in Engineering.*

Day Classes.	1911-12	1912-13	1913-14
Advanced Engineering	16	21	33
Senior Engineering	41	52	57
Junior Engineering	57	56	53
Applied Mechanics	69	60	75
Civil Engineering (Senior)	7	18	11
Civil Engineering (Junior)	15	9	12
Agricultural Engineering	4	2	5
Drawing (Advanced)	22	37	41
Drawing (Senior)	47	47	42
Drawing (Junior)	64	58	62
Laboratory (Senior)	26	40	50
Laboratory (Junior)	60	54	57
Totals for day classes	428	454	498

Fig. 2, on Plate IV., illustrates the power-station and the various prime movers, &c., in it, arranged specially for instructional and research work. There are in this station electric transformers reducing the potential of the current from the public supply mains; a high-speed enclosed compound steam-engine, driving a dynamo, with its surface condenser and pumps; a horizontal Robey engine and dynamo for electric lighting and experimental purposes; an experimental vacuum chamber, and other apparatus.

Figs. 3 and 4, on Plate IV., are views from opposite ends of the new hydraulic laboratory, which covers a floor space of about 2600 sq. ft., and is equipped with recent examples of hydraulic machines. The apparatus includes a multi-stage electrically-driven turbine pump, having a maximum speed of 2300 revolutions per minute and capable of delivering 10,000 gallons of water per hour against a head of 210 ft.; a single-stage high-lift centrifugal pump, also electrically driven, delivering 15,000 gallons per hour against a head of 100 ft.; a steam-driven direct-coupled centrifugal pump, having inlet and outlet mains, 6 in. in diameter, and delivering 36,000 gallons per hour; and a small pulsometer pump, as well as other machines.

Water raised by the above pumps may be used for operating various water-turbines, of which the following are at present installed:—a Thomson inward-flow turbine; an impulse turbine of the Gerard type; a Pelton wheel, with interchangeable cups and nozzles, arranged for a maximum head of 250 ft.; a mixed-flow pressure turbine, with vertical shaft, suitable for working under low heads of from 7 ft. to 12 ft. Of the same capacity as the mixed-

flow turbine is a water-wheel for approximately similar heads, capable of being operated as a high-breast, a low-breast, or an overshot wheel.

All the above turbines are specially arranged for experimental work under varying conditions, suitable measuring-tanks, gauges, brakes, &c., being provided. The centrifugal pumps, for example, are supplied with alternative impellers and vortex passages, and the multi-stage pump can be operated with one, two, or three stages in series. Each turbine or motor has its own separate tail-race and measuring-tank, so that the machines are entirely independent of one another. Tanks for "gauging" experiments, for the flow over weirs and through orifices, on a larger scale, are installed; and also apparatus for investigating stream-line flow, reaction of jets, friction in pipes, loss of head in pipes and bends, &c. Amongst the apparatus for measuring large quantities of flowing water are a precision-meter, with mechanical integrator, a Venturi meter, a Kennedy meter, and various arrangements of tanks, with notches and floats or point-gauges. Three large mains—two 6 in. in diameter and one 5 in.—extend the length of the laboratory, and communicate with a tank of 1000 cub. ft. capacity on the roof of the building. Three feet below the ground-level is a lower tank 3 ft. wide, which also extends the full length of the main laboratory. In addition there are such accessories as cement-testing machines, and, as seen in Fig. 3, tables and benches for carrying out various operations. In addition, there is a smaller research laboratory on the upper floor, reached by the spiral stair seen in Fig. 4.

The research work in the Hydraulics Laboratory has included investigations into the efficiency of centrifugal pumps, investigations of the effects of "whirlpool chambers," guide-blades, and varying blade angles on the efficiency of high-lift single and multi-stage centrifugal pumps; comparative efficiency of various types of hydraulic motors; further investigations into the circumstances which determine whether the flow of water in pipes shall be stream-line or turbulent. Experiments have also been made on air-pumps for the purpose of investigating the influence of water on the effective capacity of air-pumps of various kinds, and of the weight of air discharged with varying speeds and effective capacity of pump. Data have been accumulated as to the hydraulic resistances in surface-condensers, including a practical determination of the losses due to friction in condenser-tubes and headers, losses at entry to and discharge from tubes, and in the transverse flow between tube-plates and condenser-ends. Experiments to determine the coefficient of discharge for air flowing through sharp-edged orifices have also been conducted.

The Mechanical Laboratory is illustrated by Figs. 5 and 6, on Plate V. The central feature of the former view is the experimental engine, which was designed by Professor Weighton, and, when erected, was the largest and most complete engine for this work, and is believed to-day to hold a position no less significant. Apart altogether from the great variation in the working conditions provided for in the design, credit is due to the makers, as forty-six firms were employed to supply the units for the construction of the engine, and all these were worked into place without any trouble. Primarily the engine is of the quadruple-expansion type, but is so arranged that it can be worked as a simple, compound, or quadruple-expansion engine; spare liners, too, are provided, in order that the engine can work at different ratios of cylinder diameter and expansion. It can be adapted for the solution of almost every conceivable problem, as has already been suggested by the variety of tests carried out and enumerated. It is fitted with an hydraulic dynamometer of the Froude type, but designed by the Professor and made at Tyneside many years ago; one-half the torque is by gravity weight, and the other half by spiral spring. There is a recording apparatus associated with the dynamometer. The first kinetic air-pump ever made is in use, and is driven by a De Laval turbine. There is also, in connection with the experimental engine, a "Contraflo" condenser, in addition to the usual condenser incorporated in the back columns of the engine. The experimental engine has also an air-indicator to show automatically and continuously the air passing through the condenser and pump. An interesting feature in Fig. 5 is a Parsons turbine with a flat condenser suspended to the roof girders. Beyond this there are small experimental steam air-compressing engines, such as are used for charging torpedoes. Behind them are two sets of internal-combustion engines worked by producer-gas and by oil. On the left side of the view are seen work-benches, a vacuum-gauge tester, and a part of the 100-ton Buckton-testing-machine. This latter is better seen on the right side of Fig. 6, which is a view of the same laboratory from the opposite end. In front of it, however, is a 10-ton testing-machine, and beside it a crank-shaft for a Diesel engine recently erected. On the left of the view is a small gas-producing plant, associated with the internal-combustion engines seen beyond it, and already referred to. In the distance, in the centre of the view, is the steam air-compressing plant, together with the Parsons turbine with the flat condenser, and beyond the kinetic air-pump and the experimental engine just described. The latest addition to the laboratory is a one-cylinder vertical Diesel oil-engine, capable of working on the four-stroke cycle or the two-stroke cycle, the power under the former condition being 50 brake horse-power, and under the latter condition 100 brake horse-power. This engine has been supplied, on very favourable financial terms, by Messrs. Carels Frères, of Ghent, and is of a type which has recently been fully illustrated in ENGINEERING. This latest addition gives promise of very interesting work being carried out, as many variations in operation are possible, even although there is only one cylinder. It will be seen from the equipment that marine engineering occupies a large part of the curriculum of the laboratory, and it may be added that this subject has always been a special feature of Armstrong College.

As regards the Naval Architecture Department, which is under Professor J. J. Welch, formerly of the Admiralty, the funds are largely provided by subscriptions of the shipbuilders and engineers of the district, and are administered by a Committee of the subscribers acting in conjunction with the Council of the college. Day courses of study are arranged to suit the requirements of the University for degrees in applied science. For a "pass" degree three years of study are required, of which the first year is spent on training in general science, and the two later years chiefly on professional and allied subjects. To obtain a degree with honours, an additional year of professional study is required. There are also post-graduate and research courses. Diplomas are granted to students who do not enter for the university degrees, but who qualify in modified courses of professional studies. It is found that the most successful students are those who have had some practical experience of shipyard or office work before coming to the college. In some cases students take their first year of college on leaving school, but go into works for a year or more before taking up the professional part of their studies, and this arrangement also gives good results.

British Graduates in Honours in Naval Architecture are now eligible as candidates for posts as Probationary Assistant Constructors attending the Admiralty courses of study at the Royal Naval College, Greenwich. Many of the shipbuilding firms of the North-East Coast district are willing to give students practical experience in works or drawing-office during the "long vacation" (July, August, September), and on leaving college most of the British students find places in British establishments. Some of them have risen after a few years of practical experience to posts of responsibility in the technical and scientific departments; others have secured appointments as surveyors with the registration societies. A number of foreign students have been sent to Armstrong College by their respective Governments, and these, after leaving, ultimately pass into the constructors' departments of their respective countries.

The scientific investigations of the "Bulkhead Committee," appointed after the Titanic disaster, are being carried out by a staff working under the direction of Professor Welch in the premises of the College; and the staff engaged upon this work includes several former students of this department, most of them being graduates. One of the present holders of the Institution of Naval Architects Post-Graduate Scholarships (200*l.* a year) is Mr. P. Y. Brimblecombe, whose paper, on "The Stability of Ships in Damaged Conditions," was read at the recent spring meetings of the Institution. Mr. Brimblecombe is continuing his research work for another year. There are also courses of study arranged for evening students. These are largely attended by workers in the shipyards and drawing-offices, and in the case of some firms in the district, promotion in position and pay is made to depend to a considerable extent on attendance at such evening classes, and upon the results of the college examinations. The complete courses extend over a period of five years, and the classes are held from the beginning of October to the middle of the following May. Students are prepared for the Board of Education's examinations in naval architecture, and the college also holds its own examinations at the end of each session. The Shipwrights Company awards 25*l.* each year in prizes to these students. There is no doubt about the excellent results which have come from the encouragement given by local employers to this class of student. From among them have risen some of the best young men to take the more complete training given by the university courses in the day time.

There is also a mining laboratory, in which there are rock-drills, air-compressors, and apparatus on a large scale for testing the explosive nature of coal-dust. The professor of mining and surveying is Professor Henry Louis, D.Sc. The electrical department is under Professor Wm. M. Thornton, D.Sc., and there is included a fair-sized laboratory with all the ordinary electrical machinery required for a liberal course of training. Thus while the mechanical side and naval architecture necessarily preponderate, all departments of industrial activity are embraced in the very comprehensive scheme of this progressive and successful institution.

THE PANAMA CANAL.—No. XI.

GATUN HYDRO-ELECTRIC STATION.

IN the course of this series of articles we have frequently made mention of the electric control and operation of the various machines, the electric supply for the towing-locomotives, for lighting, repair-shops, and other purposes. The required power is to be obtained from two sources—mainly, as a matter of fact, from a hydro-electric plant situated at the Gatun spillway, while a stand-by steam-station will be maintained at Miraflores. A description of the spillway was given in No. 4 of this series of articles,* at which time we also gave a brief account of the power plants, more particularly that at Gatun. We now propose to give a rather more detailed account of this plant, and illustrate it with Figs. 195 to 202, Plates VI. and VII., and page 13.

The Gatun power-station is at present built for a capacity of 6000 kw., with provision for increasing this up to 12,000 kw. if it be decided later to operate the Panama Railroad electrically. It is situated below the spillway of the Gatun Dam, and will utilise an effective head of about 75 ft., though this will be increased in times of high flood, and diminished slightly during a dry season. Water is drawn off from the Gatun Lake through a forebay, the position of which is shown in Figs. 95 and 110,† and to which water is admitted through passages 12 ft. wide, fitted with wrought-iron grids 29 ft. 7 in. high. At present three pipe-lines only are being installed, though provision is made for six. They were shown under construction in Fig. 111,‡ and in a more complete state are illustrated in Fig. 195, Plate VI., herewith, the head ends of the other three showing in the distance at a point just below the forebay. Cast-iron head-gates 10 ft. 6 in. in diameter, with bronze seatings, control the admission of water to the pipe-lines. These gates have two screwed steel stems, on which work bronze nuts fitted with steel bevels, the latter being driven by a 15-horse-power 220-volt alternating-current motor with a speed of 750 revolutions per minute. The motor is placed between the stems, its shaft being extended to them on either side. Hand-operating gear is also provided. The control arrangements are such that when the gate-motor switch is closed at the power-house, the gate being closed and the pipe empty, the motor will commence to open the gate until the admission is sufficient to fill the pipe in about five minutes. On this rate of admission being reached a limit-switch opens and stops the motor. The gate remains in this position until the pipe is full and the water has risen in the 36-in. air-vent pipes

* See ENGINEERING, vol. xcv., page 836.
† *Ibid.*, page 830 and Plate LIV.
‡ *Ibid.*, page 833.

(shown in Fig. 111, already referred to) below the gates. A float-switch then comes into action, closes the motor circuit, and the gate is fully opened, the limit-switch preventing over-travel. The gate is closed by reversing the main switch at the power-house. The pipe-lines have been previously described. They are 10 ft. 6 in. in diameter, and have an average length of 420 ft., and after being riveted up at the site have been covered on the outside with concrete. They are taken to the power-house on the side of the spillway channel, with 90-deg. bends of a radius of 70 ft., as may be seen in Fig. 195. Provision is made on each pipe-line for testing the flow with a Pitot tube while it is in service. A pair of portable tubes for taking readings in the pipe at 90 deg. to each other have been furnished. Each pipe has two 6-in. saddle nozzle connections, arranged at 45 deg. to the vertical, and from these two Pitot-tube supports extend across the pipe. These supports form guides for the Pitot tubes. They are fixed in the pipe, but are easily removable. The 6-in. outlets are fitted

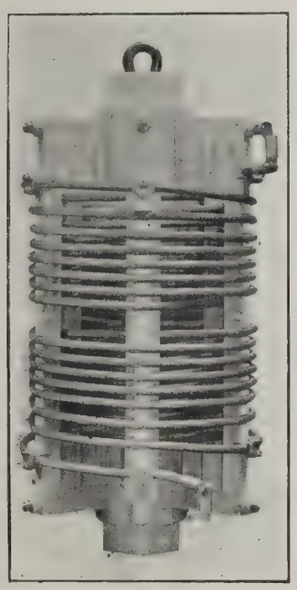

FIG. 201. REACTANCE.

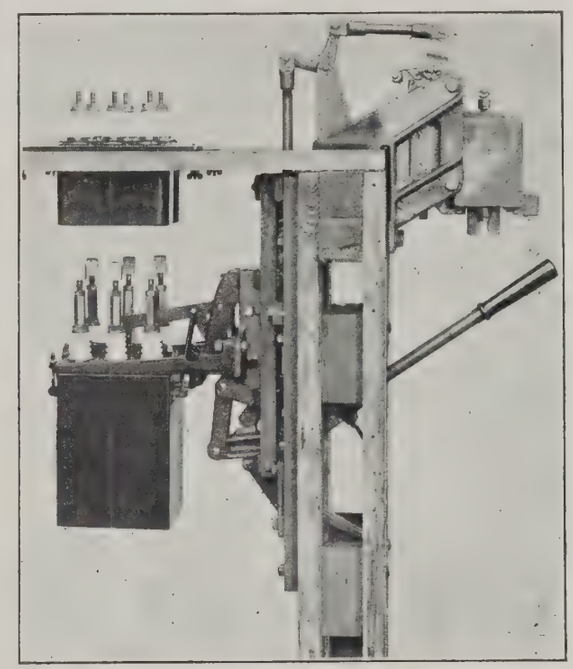

FIG. 202. SOLENOID-OPERATED 2500-VOLT SWITCH.

with gate-valves, and have tongued and grooved flanges, matching the base of the Pitot-tube apparatus. The latter may be bolted to the outlet, the gate opened, and then the tube pushed into the pipe. The tubes are arranged to measure both the static and velocity heads, the readings being obtained by means of U-tubes.

The generating units consist of three 2000-kw. machines, driven direct by Francis turbines with 50-in. runners. Under the 75-ft. head, and running at a speed of 250 revolutions per minute, the turbines develop each 3600 horse-power. The centre of the runner is 25 ft. above the tail-water. The turbine-casings will be seen in place in Fig. 195, while in Fig. 197, Plate VII., we give a larger illustration of one of these turbines, and in Fig. 198 a drawing showing a generator unit complete. The turbines are of the spiral-casing type, and above them are distance-rings carrying the electrical machines. The revolving parts of the turbine and generator are all mounted on a shaft made in one piece, and are suspended from a roller-bearing in the top of the casing.

The suspended weight is about 32 (short) tons, but the runner is designed to exert an upward thrust of about 22,000 lb. when working at full capacity, and the bearing is therefore relieved to this extent. Oil for this bearing is supplied by a lubricating pump geared to the main turbine-shaft, the surplus flowing into a tank, from which the pump takes its supplies. The turbine wheels are of bronze, and weigh about 7000 lb. each. They are finished all over. The governor gear, shown to the left hand in Figs. 197 and 198, is of the Pelton oil-pressure type. The oil pressure for the governors is supplied by two Pelton rotary pumps driven by 10-horse-power alternating-current motors at a speed of 375 revolutions per minute. Each pump is capable of supplying the governors of all three units. The governors, driven by bevel-gears off the main shaft, are furnished with small electric motors for varying the speed of the main units for synchronising purposes. They are also arranged so that the permanent drop in speed from no load to full load may be varied, between a range of 5 per cent. drop to constant speed from friction load to the maximum. Hand control is also provided. The wicket-gates are steel castings finished all over. The gates are all connected with a ring controlled by the governor. The water-passages on either side of the movable gates are fitted with renewable steel plates. The discharge from the turbines is through steel-lined concrete tubes, 71 in. in diameter at the turbine, but increasing to an elliptical section of 9 ft. by 17 ft. at the outlets. The discharge-tubes embody 90-deg. bends. The linings are $\frac{1}{4}$-in. steel plates.

Directly above the turbines are three-phase 25-cycle generators of the revolving field type, of a guaranteed continuous capacity of 2000 kw. at 0.8 power factor, 2200 volts, and 250 revolutions per minute, and an overload rating of 2500 kw. at 0.8 power factor for two hours. The stationary armatures are bolted to heavy cast-iron distance-rings some height above the turbine. The weight of 32 short tons given above for the load taken by the thrust-bearing includes the weight of the generator field and exciter armature. The exciter is arranged just below the generator. It is a 50-kw. machine at 125 volts. Each exciter is capable of furnishing exciting current for two generators under maximum guaranteed load. The exciter-magnet frame is attached to a casting bolted to the distance-rings. By means of clamp-screws the exciter-magnet frame may be attached to the revolving field of the generator, and the whole removed together for repairs.

The generators under official test showed an efficiency of 95.1 per cent. at 2000 kw., 0.8 power factor; of 94.3 per cent. at 1500 kw., 0.8 power factor; and 92.5 per cent. at 1000 kw., 0.8 power factor. The guaranteed temperature rises of 40 deg. Cent. above room temperature, 25 deg. Cent. under continuous operation at full load, and 55 deg. Cent. after two hours at 25 per cent. over-load, were easily met.

The generator sets are accommodated in a station building on the side of the spillway channel, as shown in Fig. 196, Plate VI. The building is unpretentious in style, the walls being of poured concrete 30 in. thick. It measures 61 ft. by 137 ft., being capable of extension, and has an extreme height of 74 ft. The roof is of reinforced-concrete slab construction, covered with Spanish red tiles, and projects beyond the walls for 13 ft. 2 in. A section of the building is shown in Fig. 199, from which it will be seen that the interior is clear to the roof, except for galleries. The floor area is divided into a pit for the three generator sets, a main floor, and two galleries devoted to switch-gear, &c. The turbine-pit is 6 ft. below the main floor. Below the main floor is a basement, containing air-compressing and oil-pumping plant. The main floor is laid with rails, so that 30-ton cars can be brought into the building under the overhead crane, for handling heavy parts. The switch-gear galleries extend the entire length of the building on one side, and at one end are two galleries, used respectively for offices and a machine-room. The switch-gear galleries are shown in section in Fig. 200, Plate VII.

In addition to the direct-connected exciters, two others, motor-driven, are provided. These each consist of a 100-kw., 125-volt generator, running at 500 revolutions per minute, direct connected with a 150-horse-power, 2200-volt, 25-cycle squirrel-cage induction motor. These exciters can also be used for charging the control batteries. The main generator windings are rigid enough to stand a short-circuit under full load, but reactances have been provided to reduce the shock. These will also serve to make synchronising easier and safe. One of these current-limiting reactances is shown in Fig. 201, annexed. They are provided with concrete cores.

The current is actually transmitted across the Isthmus at 44,000 volts, step-up transformers being provided at Gatun and in connection with the stand-by station at Miraflores, and the necessary step-down plants at these places and at Cristobal and at Balboa. The power plants generate and distribute only 2200-volt current. The system of connection throughout is the double-bus double-switch method, any oil-switch being capable of disconnection for repairs and cleaning without interrupting the circuit.

The main switchboard is of the bench type, with a vertical rear board for relays and instruments and control-battery equipment. The space between the front and rear boards is enclosed with metal grill-work, with doors at both ends. Above the switchboard is a second storey, accessible by ladder and accommodating the electrically-controlled generator and exciter rheostats. Of the eight bench panels, one controls the exciters, the next three the generators, and the remaining four the feeder-circuits. A generator voltage-regulator, transferable to either of the two sets of busses, is installed on a separate pedestal, which also carries the synchronism indicators and clock. The exciters are controlled from the bench, but the electrically-operated exciter and field switches are mounted on a separate board located so as to keep the connections as short as possible. This eliminates the exciter busses and the main connections from the control-board, but leaves the control of the whole equipment in the hands of the operator. On the upper of the two galleries, shown in section in Fig. 200, Plate VII., near the end of the building arranged for possible extension in the future, are the control-board, generator reactances, compartment for generator current and potential transformers, and the generator oil-switches. From the latter connections pass through the floor to the busses on the gallery below. On this gallery are also the feeder oil-switches, the compartment for the instrument transformers and the cable bells. Below, on the main floor is the cable vault, to be seen in Fig. 199.

The 2200-volt oil-switches are solenoid operated and fitted with disconnecting gear to facilitate cleaning and repairs, all live parts being completely covered. One of these switches is shown with the disconnecting device open in Fig. 202, annexed. These and the hand-operated switches were described in a previous article.* Briefly, it may be said that by a lever and toggle gear, mounted on vertical guides, the oil-switch is raised or lowered. Above the oil-switch is a stationary base fitted with disconnecting studs, which are coupled to the high-tension leads. The studs carry underneath contact-fingers, which engage with contact-blades fitted on the top of the oil-switch, when the latter is raised by the lever. When the oil-switch is lowered it is completely isolated from the circuit; when raised it is latched in position. An interlock prevents an oil-switch being raised or lowered unless its contacts are open. In the case of the solenoid-operated switches, the solenoid is stationary, and the con-

* See ENGINEERING, No. X., page 241 *ante*.

necting mechanism includes a vertical slotted link, allowing the switch to be raised or lowered without disconnecting the solenoid gear.

Of the plant at the Gatun station, the turbines, as already noted, were built by the Pelton Water-Wheel Company, New York, who, in fact, supplied the whole hydraulic equipment, including gates, pipe-lines, Pitot tubes, governors, &c. The electrical portion of the installation, including the generators, switch-boards, transformers, head-gate motors, switches, and accessories, were designed and manufactured by the General Electric Company, Schenectady, to whom, through the British Thomson-Houston Company, Limited, we are indebted for the foregoing particulars.

We have on several previous occasions referred to the arrangements made for transmission across the isthmus and for transforming at the locks, &c., and need not enter again into this work. Recent advices from Panama stated that the hydro-electric station at Gatun was expected to be in service by the end of May. The transformer sub-stations at Gatun, Miraflores, Cristobal, and Balboa are fairly well advanced, except that at Balboa. Eighty per cent. of the electrical equipment had been received in May, and installation has commenced at Gatun. By the beginning of May, 903 out of 917 track span-bridges for the transmission lines had been erected and work on the conductors was in progress.

INDUSTRIAL NOTES.

THE annual meeting of the Wolverhampton Chamber of Commerce was held on Wednesday, the 24th ult., when the president, Mr. W. Johnson, in moving the adoption of the annual report, called attention to the disastrous effects which labour troubles had upon the trade of the country. Among the more clear-sighted labour leaders there were some, he said, who recognised that strikes had a most injurious effect on the workers themselves. He then dealt with the question of inland waterways, and said that the Chamber had always taken an immense interest in the matter of water carriage in this country, especially as it applied to the immediate district. He was glad they had enlisted the interest of some members of the Wolverhampton Corporation, and added that there was a growing opinion that something ought to be done to improve the waterways. In regard to these, Colonel A. McBean expressed the hope that the Wolverhampton Corporation would look upon the subject of inland waterways from a national and not from a local or parochial standpoint. If this question had taken shape some years ago, the extension of the waterways in the district might have saved the removal of large industries to the coast. To-day the Staffordshire district was being fed by more foreign iron and steel than those interested in iron and steel cared to think about. Foreign competitors were beginning to look upon Staffordshire as their natural market; in fact, as a market to which they had more right than we had ourselves. Foreign competition, he added, was becoming an immense monster, and it must be faced without political sentiment.

A number of points were dealt with at the congress of the International Federation of Postal and Telegraph Servants, held at Caxton Hall, Westminster, on Thursday, the 25th ult. The delegates present represented a very large proportion of postal, telegraph, and telephone employees of Great Britain and Continental countries. The British postal workers' society demanded that all Governments should establish and maintain the eight-hour day principle as an example to other employers of labour, and the concession of full civil and political freedom for employees of the State. They also expressed the opinion that the nationalisation of public services, such as the Post Office, was not necessarily advantageous to the employees and the working class, unless accompanied by steadily-increasing democratic control, both by the employees and the representatives of the working classes in Parliament.

The question of a universal language was also raised by Mr. Koch, a Swiss delegate, who urged the point very strongly, stating that a universal language would better enable the workers to fraternise, thus increasing their solidarity and strength. Some delegates agreed, whilst one stated that if they adopted either Esperanto or Ido they would simply be adding to the existing Babel. It was only in the interests of the "ignorant Englishman who lived on an island," added the delegate, that the universal language proposals were brought forward. Their immediate effort should be to push forward for economic and political emancipation. When they had done that they should be free to educate themselves, and then they would have no need for a "bastard language." A resolution in favour of the fusion of Esperanto and Ido was eventually carried. This resolution has no weight, and will satisfy nobody, least of all the advocates of either of the two universal languages.

A French delegate moved that a thorough inquiry be made regarding the occupational illnesses to which postal servants were subject. The matter, he said, should be regarded in an international spirit, as it affected all postal workers. If they had post-offices in France like those in London, they were inclined to think long and severe illnesses would disappear.

Mr. W. B. Cheeseman, on this point, said he hoped and believed that by the work of the society they were on the way to the elimination of consumption, but other diseases affecting the nerves of the workers were still prevalent. He mentioned the noise and vibration of machines, and more particularly speeding-up methods of work, as probable causes. "We have," he added, "a comparatively large number of men who have been obliged to go to lunatic asylums because their minds have become unhinged in consequence of the strain of their work." It was necessary, he stated, that an inquiry, should be made at once. Medical officers, he alleged, were unwilling to state deliberately what the men were suffering from, and common diseases were often put down as being the cause of illness, when, as a matter of fact, they were due to nervous complaints which had developed. The motion was agreed to.

Mr. T. W. Casey, the general secretary of the Yorkshire Winding Enginemen's Society, had interviews last week with the Home Office respecting a new code of shaft signals; a compromise has been arrived at in the matter, which does not appear generally to give satisfaction. The men were determined that some alteration should be made in the new code issued by the Home Office, otherwise they would not work it. The main point at issue had reference to the signals for winding-men. Under the new code the winders declared it was impossible to wind men against men without serious danger, the reason being that whilst on the one hand the signal 3 to the engineman meant that he could draw the cage away from the bottom, another similar signal from the pit bottom meant that he must keep the cage stationary until he received the signal 1. This was very confusing, and the result of the ballot of the Winders' Society clearly showed that the men would not work to this signal.

Conferences have been held in London with Sir Richard Redmayne (Chief Inspector of Mines), the Right Hon. Mr. McKenna (Home Secretary), and other Home Office officials. The winders asked that in regard to the signal of 3, when men were ascending or descending, this signal should be a warning that men were going to "ride" the shaft, but that before the cage was allowed to move there should be a separate signal of 1 given after the 3. The Home Secretary decided in the men's favour, and granted the additional signal 1. We may add here that the men have throughout received the united support of the colliery-owners in their desire to remedy their grievance.

Mr. Casey, while expressing regret that they could not retain the old signal of 3 and 2—which he still considered to be by far the best and safest—agreed to recommend the winders to accept the 3 and 1 signal in each case of winding men, whether ascending or descending the shaft. He had received an intimation that the Secretary of State was agreeable to the additions to the code on the lines suggested, and would have the alterations incorporated in the code in the proper way.

The coalmen on the Great Northern Railway have been agitating for some considerable time with a view to obtain a revision of their conditions of service. The conditions under which they work include, it is stated, a 72 hours week when on day duty, and 74 hours when on night duty, with no deduction for meal-times. They are paid at the rate of 2¼d. per ton, and at some depots as much as 2300 tons a week are dealt with. This has to be handled by the coalmen, who have to transfer the coal from the staithes to the engines. The men demand a 48 hours week, and the piece-work rate to be advanced by 1d. an hour, also one week's holiday, with pay and a free pass.

The company declined to agree, and the matter was placed before Judge Parry, who has now given his award as follows:—A 55½ hours week, exclusive of 1¾ hours a day for mealtimes, an advance of ¼d. per ton all round, three days' holiday with pay each year after a man has been five years in the company's service. The award applies to all the coalmen throughout the Great Northern Railway system. The new conditions will remain in operation for twelve months.

A dispute regarding non-unionists, which had arisen between the Warehouse Workers' Union and Messrs. Wilson Brothers, Garston, has been settled by Sir David Harrel, the Board of Trade arbitrator. In his award Sir David Harrel states that Messrs. Wilson's claim to the effect that they should continue to maintain their attitude of neutrality and impartiality as between unionists and non-unionists was admitted by the work-people. The workers' request that notices should be placed in the works that the company did not view with disfavour the employment of trade unionists was agreed to by the employers. All parties were agreed as to the procedure necessary in the case of persons who were undesirable, "in so far as undesirable meant persons of immoral character, of objectionable personal habits, or users of obscene or improper language." The claim of the work-people that the firm should be forced to take any steps which might be interpreted as an inducement to persons to join the union appeared, in the arbitrator's opinion, to be inconsistent with the employers' attitude of neutrality and impartiality as between unionists and non-unionists.

We are informed that the concessions which were offered some weeks ago to 'busmen by the London General Omnibus Company, and were accepted by the Licensed Union of Vehicle Workers on behalf of its 15,000 members, will cost the company about 200,000*l.* per annum.

A meeting of delegates of the members of the Railway Clerks' Association from all parts of the North-Eastern Railway system was held at York on Saturday, the 27th ult., to consider further their demand for improved conditions and increased salaries. Mr. A. J. Best, Darlington, presided.

The association some time ago promulgated a demand for a salary scale rising to 150*l.* at 37 years of age; in reply to this, the company introduced a new scale, which, while it accelerated the progress of the younger men, had no effect upon the majority of the senior men.

After discussion, a resolution was passed unanimously expressing (*a*) indignation at the failure of the company to introduce a standard scale on the lines indicated, and condemning the existing system; reiterating (*b*) the demand "that the debased scale in operation in the telegraph department shall be withdrawn, and these clerks shall have salary conditions identical in all respects with those of their colleagues in the other departments;" (*c*) the resolution further expressed surprise and regret that the management still adheres to the decision to exclude the shop clerks from the provisions of the scales for salaried staff; (*d*) the meeting, the resolution continued, "again asserts the claim for recognition of the Railway Clerks' Association, urges the executive committee of our organisation to lose no opportunity of pressing for this right, which has been accorded to those engaged upon the manipulative and operative side of the business, and pledges to them the united support of the clerical staff in any action they may see fit to take;" (*e*) the meeting authorised and instructed the Salaries Movement Committee to seek at once another interview with the Board of Directors, "with a view to placing the whole position before them once more, in the light of the evidence as to actual North-Eastern salary conditions which has recently been obtained, and the further evidence as to salaries in the Civil Service, the Postal Service, and other first-class businesses, which has become available since the interview on July 24, 1913.'

We are informed that the strike of trawler engineers at Fleetwood, to which we referred in our last issue, has been satisfactorily settled. Last week representatives of the Fishing-Vessel Owners' Association and the Amalgamated Engineers' and Firemen's Union held a conference, the result of which was the reinstatement of the discharged engineer.

On Friday last, the 26th ult., evidence was given before the Select Committee on behalf of the Federation of Laundry Associations, who are opposing the Bill for the confirmation of the Provisional Order to include calenderers and machine-ironers in laundries within the Trade Boards Act. Sir J. Compton Rickett occupied the chair.

Mr. J. Stark, secretary of the Federation, complained of the competition of small laundries which were not under Home Office inspection. He pointed out the risks that were run owing to the conditions under which clothes were dealt with in such places. He instanced a case in which chicken-pox had been contracted, and another case where washing was done in a house from which children suffering from scarlet fever had been removed. He explained that variations in wages in the factories were due to the capacity or lack of capacity on the part of the workers. The trade, he added, was quite willing to pay higher wages if a better class of worker could be obtained.

INTERNATIONAL FEDERATION OF CONSULTING ENGINEERS.—The second international congress of consulting engineers will take place at Berne, Switzerland, from the 15th to the 22nd inst. A programme of the proceedings has been issued. All information concerning the congress can be obtained from Mr. de Herbais de Thun, 18, Rue Marie-Thérèse, Brussels.

NOTES FROM THE NORTH.

GLASGOW, Wednesday.

Glasgow Pig-Iron Market.—Last Thursday morning the pig-iron market was again dead idle. In the morning Cleveland warrants were a shade easier, with sellers at 51s. 3d. cash, 51s. 5d. one month. and 51s. 6½d. three months, while in the afternoon these quotations were barely maintained, and sellers named 51s. 2½d. cash, 51s. 4d. one month, and 51s. 6d. three months. There was no improvement in the market on Friday morning; prices of Cleveland warrants were stationary, and no dealings were recorded. At the close sellers quoted 51s. 2½d. cash, 51s. 4d. one month, and 51s. 5½d. three months. The afternoon session was dull, and business amounting to 2500 tons of Cleveland warrants was done at 51s. 1d. cash and 51s. 4d. three months, and closing quotations were called 51s. 1½d. cash, 51s. 3½d. one month, and 51s. 5d. three months. On Monday morning the market was again quiet, and business was limited to 1000 tons of Cleveland warrants at 51s. 1d. and 51s. 0½d. cash. Closing sellers quoted 51s. 1d. cash, 51s. 3d. one month, and 51s. 4d. three months. In the afternoon the tone was a shade easier, and the minimum of dealings took place—namely, one Cleveland warrant at 51s. cash, the session closing with sellers quoting 51s. 0½d. cash, 51s. 2½d. one month, and 51s. 3½d. three months. On Tuesday morning the market was quite idle, and sellers of Cleveland warrants quoted 51s. 1d. cash, 51s. 3d. one and three months. The tone was steady in the afternoon, when 1000 tons of Cleveland warrants changed hands at 51s. 1d. twenty-one days. At the close sellers quoted 51s. 1d. cash, 51s. 3d. one month, and 51s. 3½d. three months. When the market opened to-day (Wednesday) the tone was stronger, but no dealings were recorded, and sellers' quotations for Cleveland warrants were 51s. 1½d. cash, 51s. 3d. one month, and 51s. 5d. three months. The afternoon session was another blank as regards business, and although buyers' quotations were a shade easier, sellers of Cleveland warrants made no change in their prices.

Sulphate of Ammonia.—An improving demand has been noticeable in the sulphate of ammonia market during the past week, and buyers seem more inclined to book a little ahead. The price is firmer, and for prompt delivery the current quotation is now from 10*l.* 12s. 6d. to 10*l.* 15s. per ton, Glasgow or Leith, and for forward lots prices are also the turn better.

Scotch Steel Bars.—The quietness in the Scotch steel trade continues, and there is not the slightest sign of any improvement. With such a scarcity of orders as has prevailed for some time, it is wonderful how some of the establishments have managed to keep going so long. The heavy importation of general material from the Continent has been very severely felt, and instead of the usual stir and bustle at this period of the year, on the eve of the holidays, there is an absence of pressure for deliveries, and the day for closing down will not be unwelcome. Specifications are only for small lots, and inquiries are limited and also of small volume. Plates, sheets, and sectional material are all alike in this category, and the outlook is not promising. The export trade is keeping up fairly well, and although some of the markets are a little unsettled, one or two others are consuming quite respectable quantities of material. Australia and New Zealand are each taking up a considerable tonnage, while India, South Africa, and Japan are moderate buyers. Prices all round are steady, but Continental quotations are about as low as ever.

Malleable-Iron Trade.—The West of Scotland malleable-iron makers report no improvement, and are still suffering from the heavy shipments of material from the Continent, the prices quoted for which they cannot look at. They are picking up moderate orders here and there, and are managing to keep running on a reduced number of shifts on these hand-to-mouth lots. The price of "crown" bars is unchanged.

Scotch Pig-Iron Trade.—Although there has been no notable increase in the demand for Scotch pig-iron, orders have been coming in exceedingly well, and stocks show little increase. Consumers in the South continue to purchase fair quantities, and there is almost certain to be an increased request during the next two weeks, before the annual holidays commence. Export departments are also fairly well employed shipping the noted local brands, and inquiries, though only moderate, are encouraging. The following are the market quotations for makers' (No. 1) iron:—Clyde, 67s.; Calder, Gartsherrie, Summerlee, and Langloan, 67s. 6d. (all shipped at Glasgow); Glengarnock (at Ardrossan), 70s.; Shotts (at Leith), 68s. 6d.; and Carron (at Grangemouth), 68s.

Scotch Shipbuilding. — The figures dealing with the Scotch shipbuilding output for the past month are both interesting and satisfactory, the total being 25 vessels of 77,490 tons, made up as follow:—

	Vessels.	Tons.
The Clyde	20	73,680
The Forth	1	3,100
The Tay	1	100
The Dee	3	610
Total	25	77,490

The Clyde output is a good bit ahead of the return for the corresponding month of last year, which was 22 vessels, of 54,478 tons, but it has actually only been bettered on one other occasion—namely, June, 1906, when the total was 124,544 tons. This latter total was swelled by the launch of the Lusitania and the battleship Agamemnon. Dealing with the work of the half-year we find that the output—129 vessels, of 267,677 tons—is rather more than 80,000 tons down from the corresponding period of last year, and which included the Aquitania, but is the sixth highest output on record for the first half of any year. These six occasions are:—

Year.	Tons.	Year.	Tons.
1906	336,258	1912	289,586
1907	302,847	1913	348,475
1911	310,460	1914	267,677

The booking of new work during the past month was more satisfactory than during one or two of the preceding months, and several important contracts are reported. One of these has been secured by Messrs. Barclay, Curle and Co., Scotstoun, and is for a twin-screw oil-engined vessel of 8000 tons gross and 6000 horse-power, for the Russian East Asiatic Steamship Company. Most of the shipyards are still well employed, but one or two labour troubles are at present casting a shadow over the industry, and something more is likely to be heard of them in the near future. Wages, non-union labour, and an eight-hour day are the principal items which will be under discussion very soon.

ONE HUNDRED AND TWENTY-FIVE POUND CONCRETE COTTAGE COMPETITION. — The result of the concrete cottage competition, organised by *Concrete and Constructional Engineering*, will be made known in the July number of that journal, which will be issued on July 4. The exhibition of the 249 designs sent in will be held at the Surveyors' Institution (lecture hall), 12, Great George-street, Westminster, S.W., from July 6 to July 11, between the hours of 11 a.m. and 6 p.m. The assessors, it will be remembered, were Mr. Max Clarke, F.R.I.B.A., Professor Beresford Pite, F.R.I.B.A., and Mr. Edwin O. Sachs, F.R.S. Ed.

THE BRITISH FIRE-PREVENTION COMMITTEE. — The British Fire-Prevention Committee's annual report for 1913, which has been issued this week, shows the extension of its work. Originally the committee devoted itself mainly to testing, but, apart from the conduct of its testing-station, it is doing a considerable amount of advisory work for the public authorities, and latterly also work of a popular character. The first part of the annual report records what has been done as to such questions as celluloid dangers, flannelette dangers, safety from fire on board ship, portable chemical fire-extinguishers, and the formation of the committee's new technical inquiry-office. Another part is devoted to its popular work in issuing "Christmas warnings," and to the popular warning, issued through the Board of Education, as to school entertainments. Then follow a number of official data, such as recommendations or regulations officially issued by the Home Office in the matter of fire precautions.

SUBTERRANEAN RESERVOIRS IN QUEENSLAND.—In the rolling downs country of Western Queensland the artesian supply of water has rendered it possible to carry on industries dependent on water supply. Pastoralists, the western pioneers of Queensland, made fortunes forty years ago in wool, but that was because they had a series of good years. Droughts afterwards decimated these regions. Nature was kind to these early pastoralists, who depended on her to supply water and pasturage, and only assisted her by the construction of dams and tanks. There is now obtained from subterranean reservoirs an unfailing flow of water, both for drinking and irrigation. At the end of 1912 there were 1879 artesian wells in Queensland. The deepest bore is situated at Bimerah, in the central west. This has a depth of 5045 ft. The shallowest bore is at the Manfred Downs, also in the central west, which yields a supply of 2000 gallons per day. The Charleville bore has a depth of 1371 ft., and the largest flow in the State—viz., 3,000,000 gallons per day. The estimated aggregated daily flow from all bores in Queensland is 529,817,860 gallons. This supply necessitated 384.68 miles in depth of boring. In some instances the water has a high temperature, and requires to be cooled before using for domestic purposes.

ALL-STEEL CAR FITTINGS.—We have had the opportunity, in the course of the last few days, of inspecting at the Moorgate Works of Messrs. G. D. Peters and Co., Limited, Moorfields, E.C., a number of samples of interior fittings for all-steel cars, such as are being adopted now on many railways in the United States. The material included a number of steel doors, windows, sashes and frames, portions of sides, sample mouldings, &c., and we were much interested in the sharp and clean finish of the work we saw. The mouldings were particularly good, the rounding commonly present in pressed-steel work being almost completely absent, so that when finished they have the appearance of clean-cut wood mouldings. The samples of mouldings included several of very complicated profile, while the advantage of steel-work of this class was noticeable in the ease with which deep mouldings may be built up out of narrow sections by simple spot-welding. Spot-welding can, in fact, be used with advantage in a good deal of this work. The doors and windows are equally well finished, and when fitted in a car would deceive any but the most expert, unless tested by the touch. The samples are the work of the Hale and Kilburn Company, of Philadelphia, Pa., U.S.A., whose business in this and many other countries is conducted by Messrs. G. D. Peters and Co., Limited. As is well known, there has been a considerable movement in the United States with a view to substituting steel stock for the wooden passenger-cars, and the question of interior finish has thus received a great deal of attention over there. The time and thought expended has resulted in a very good product, and the samples which Messrs. G. D. Peters and Co. have to show can hardly fail to prove of interest to a large number of railway men in this country.

NOTES FROM SOUTH YORKSHIRE.

SHEFFIELD, Wednesday.

South Yorkshire Coal Trade. — Except for the best qualities, for which there is a steady demand, the house-coal trade is unusually quiet. Business at the local dépôts is on a very small scale. The turn of the month has brought a few more orders for stocking purposes, but has not materially improved the position. Pits that rely exclusively on this class of trade are only working four days per week, and some of them shorter time than this. The demand from London merchants is nothing like what it was at this time last year. The steam-coal market occupies very much the same position as it did a week ago. Big tonnages are going into consumption in the heavy industries, though the export trade is not noticeably larger. Contracting is just a little further advanced. In some cases users have succeeded in obtaining 1s. reduction on last year's figures. Forced selling is reported, though on the whole values are steady. Slacks move unevenly, but a firmer tone prevails in cheaper qualities where weakness has been most pronounced. Coke is on the down grade. Quotations:—Best branch hand-picked 15s. 6d. to 16s. 6d.; Barnsley best Silkstone, 13s. to 14s.; Derbyshire best brights, 12s. to 13s.; Derbyshire house, 10s. 6d. to 11s. 6d.; best large nuts, 10s. 6d. to 11s. 6d.; small nuts, 9s. to 10s.; Yorkshire hards, 11s. to 12s.; Derbyshire hards, 10s. 6d. to 11s. 6d.; best slacks, 7s. 6d. to 8s. 6d.; seconds, 5s. 6d.; smalls, 4s. to 5s.

Iron and Steel.—There is no difficulty in obtaining supplies of raw material. The difficulty is rather in getting sufficient orders to keep the furnaces working, despite the fact that a considerable proportion of them have been damped down. Users are coming forward very slowly with contract renewals. There is still a great deal of uncertainty as to whether the worst has been experienced in the sagging of values, and, in the absence of any definite feeling, the arrangement of forward bookings is being seriously impeded. Spot business in Lincolnshire products has been expedited by the reduction of official quotations to 52s. 6d. for foundry iron, and 50s. for forge iron. So far the change, which has long been expected, has not adversely affected the sale of Derbyshire products. A good tonnage of hematite is going into consumption. West Coast quotations are firmly held, but a slight reduction is shown in East Coast figures. Steel-makers have taken full advantage of the reduction. There is very little movement in basic iron. The slight improvement in bar iron, consequent upon wagon-building activity, is maintained. While slackness at the steel works is the rule rather than the exception, it is attributable not so much to declining trade as to such quarter-end influences as stock-taking. The gross output is much smaller, but the shrinkage has not been so severe as to give cause for genuine alarm. Cases of undiminished activity are still to be found. Heavy engineers have not only as many orders on their books as to keep them fully employed, but in a number of cases are unable to secure the requisite amount of skilled labour. The big armament firms are quite as busy. Not only are there heavy orders on hand for the British Government, but the requirements of foreign Powers, notably Spain and Russia, in connection with naval re equipment, are exceptionally large. On the other hand, railway material departments could comfortably handle a bigger volume of business. The export demand is their present mainstay. There is a fair inquiry from English corporations for tramway materials. Average activity is maintained in special steel-making, but steel billet makers report a dearth of new business. Machinery for overseas mining purposes is a busy medium, particularly for export to South Africa. Makers of files, engineers' tools, twist-drills, and wire rope have satisfactory prospects. The lighter steel trades are regularly engaged.

PERSONAL.—Mr. William C. Mountain, Sun Buildings, Newcastle-on-Tyne, states that in order to meet the requirements of his increasing practice he has opened an office in London at 66, Victoria-street, Westminster.

ALGERIAN RAILWAYS.—The receipts of the Algerian and Tunisian networks of railways last year amounted to 1,178,170*l.*, as compared with 1,017,338*l.* in 1912. The net revenue last year was 139,770*l.*, as compared with 127,160*l.* An official decree of June 9, 1914, provides that the Governor-General of Algeria is authorised to purchase the concessions of the Bona and Guelma Railway Company. The line purchased will be incorporated in the Algerian State network.

CONTRACTS.—A contract has just been awarded by the Chinese Government to the Niles-Bement-Pond Company for the complete equipment of a small-arms arsenal at Hanyang, near Hankow, China. The contract calls for the delivery of the complete equipment in about two years. This will include all of the machine-tools, jigs, fixtures, cutters, and three complete sets of gauges. All the machines and tools will be built at the Pratt and Whitney Works, Hartford, Conn.—Messrs. J. Dampney and Co., Limited, Cardiff, have recently received an order for 300 gallons of their "ApeXioR" compound from the Victoria Falls and Transvaal Power Company, Limited, their requirements for one year. This company have adopted "ApeXioR" for use in their entire plant of Babcock and Wilcox boilers.—The Preston Town Council has, after a series of tests, decided to order two Hatfield motor fire-engines, fitted with reciprocating pumps, from Messrs. Merryweather and Sons, London. The new engines will be capable of pumping 450 to 500 gallons per minute, and will each carry a 60-ft. fire-escape and a chemical cylinder for throwing a "first-aid" jet.

THE TESTING OF TURBINES AND TURBO-BLOWERS AT THE HEATON WORKS.

(For Description, see Page 3.)

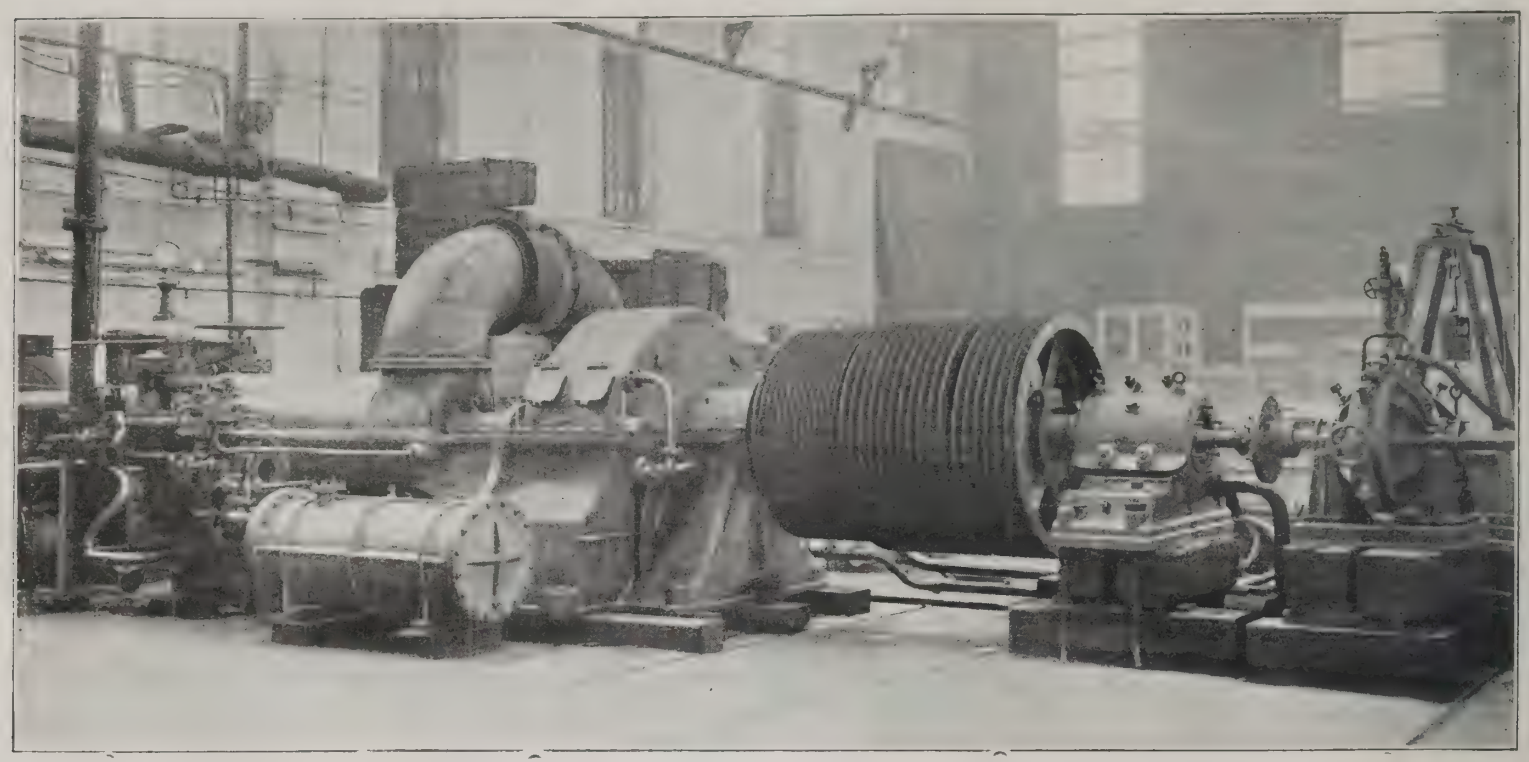

FIG. 2. GEARED TURBINES WITH ROPE-PULLEY FOR MILL-DRIVING UNDERGOING TESTS.

AGENTS FOR "ENGINEERING."

AUSTRALIA: Gordon and Gotch, Limited, Melbourne; Sydney; Brisbane; Perth. Turner and Henderson, Sydney, N.S.W. T. Willmett and Co., Townsville, North Queensland. W. C. Rigby, Adelaide, South Australia. Melville and Mullen, Melbourne, Victoria.
AUSTRIA-HUNGARY, Vienna: Lehmann and Wentzel, Kartnerstrasse.
BELGIUM: E. F. Satchell, 45, Avenue de Terneuzen, Brussels.
CANADA, Toronto, Ont.: Wm. Dawson and Sons, Manning Chambers. Montreal: Sells, Limited, 302 Shaugnessy Building, McGill-street.
EDINBURGH: John Menzies and Co., 12, Hanover-street.
FRANCE, Paris: Boyveau and Chevillet, 22, Rue de la Banque. For Subscriptions and Advertisements, Librairie B. Tignol, 53bis, Quai des Grands-Augustins, Paris. Also for Advertisements, Agence Havas, 8, Place de la Bourse.
GERMANY, Berlin: A. Asher and Co., 13, Unter den Linden. Leipzig: F. A. Brockhaus. Mulhouse: H. Stuckelberger.
GLASGOW: William Love.
INDIA, Calcutta: Thacker, Spink and Co. Bombay: Thacker and Co., Ltd.
ITALY: U. Hoepli, Milan, and any post-office.
LIVERPOOL: Mrs. Taylor, Landing Stages.
MANCHESTER: John Heywood, 143, Deansgate.
NEW ZEALAND: Gordon and Gotch Proprietary, Limited, Wellington, Auckland, and Christchurch.
NORWAY, Christiania: Cammermeyer's Boghandel, Carl Johans Gade, 41 and 43.
ROTTERDAM: H. A. Kramer and Son.
SOUTH AFRICA: Central News Agency, Limited, Head Office—Johannesburg; and Pretoria, Cape Town, Port Elizabeth, Bloemfontein, Durban, and their various branches and bookstalls throughout South Africa. Also Cape Town: Wm. Dawson and Sons, 31, Long-street.
TASMANIA: Gordon and Gotch Proprietary, Limited, Launceston; Hobart.
UNITED STATES, New York: W. H. Wiley, 432, Fourth Avenue. Chicago: H. V. Holmes, 967-968, Monadnock Block.

ADVERTISEMENT RATES.

The charge for advertisements is three shillings for the first four lines or under, and eightpence for each additional line. The line averages seven words. Payment must accompany all orders for single advertisements, otherwise their insertion cannot be guaranteed. Terms for displayed advertisements on the wrapper and on the inside pages may be obtained on application. The pages are 12 in. deep and 9 in. wide, divisible into four columns of 2¼ in. in width. Serial advertisements will be inserted with all practicable regularity, but absolute regularity cannot be guaranteed.

Advertisements intended for insertion in the current week's issue must be delivered not later than 5 p.m. on Thursday. In consequence of the necessity for going to press early with a portion of the edition, alterations for standing advertisements should be received not later than 1 p.m. on Tuesday in each week.

SUBSCRIPTIONS, HOME AND FOREIGN.

"ENGINEERING" can be supplied direct from the Publisher post free, for twelve months, at the following rates, payable in advance:—

For the United Kingdom	£1	9	2
For Canada—			
Thin paper copies	£1	11	6 ($7.65)
Thick "	£1	16	0 ($8.75)
For all other places abroad—			
Thin paper copies	£1	16	0
Thick "	£2	0	6

When foreign subscriptions are sent by Post-Office orders, advice should be sent to the Publisher.

Foreign and Colonial subscribers receiving incomplete copies through newsagents are requested to communicate the fact to the Publisher, together with the agent's name and address.

All accounts are payable to "ENGINEERING," LIMITED. Cheques should be crossed "Union of London and Smith's Bank, Limited, Charing Cross Branch." Post-Office Orders should be made payable at Bedford-street, Strand, W.C.

Offices for Publication and Advertisements, 35 and 36, Bedford-street, Strand, London, W.C.

We desire to call the attention of our readers to the fact that the above is our SOLE ADDRESS, and that no connection exists between this Journal and any other publications bearing somewhat similar titles.

TELEGRAPHIC ADDRESS } "ENGINEERING," WESTRAND, LONDON.

TELEPHONE NUMBERS—3663 and 8598 GERRARD.

READING-CASES.—Reading-cases which will hold twenty-six numbers of "ENGINEERING" may be had of the Publisher or of any newsagent. Price 6s. each.

NOTICES OF MEETINGS.

THE ROYAL SANITARY INSTITUTE.—Saturday, July 4, to Saturday, July 11, at Blackpool. For detailed programme, see page 877 of our issue of June 26.

THE ROYAL INSTITUTION OF GREAT BRITAIN.—Monday, July 6, at 5 p.m., general meeting of the members.

THE INSTITUTION OF NAVAL ARCHITECTS; THE INSTITUTION OF ENGINEERS AND SHIPBUILDERS IN SCOTLAND; AND THE NORTH-EAST COAST INSTITUTION OF ENGINEERS AND SHIPBUILDERS.—Joint Meeting at Newcastle-upon-Tyne. July 7 to 10. July 7, at 10 a.m., Reception in the King's Hall, Armstrong College, by the Earl of Durham, K.G., and members of the Reception Committee, and an address of welcome by the Lord Mayor of Newcastle-upon-Tyne and the Hon. Sir Charles A. Parsons, K.C.B., F.R.S., President of the North-East Coast Institution of Engineers and Shipbuilders. The following papers will then be submitted by the Institution of Naval Architects:- (1) "On the Protection of Battleships Against Submarine Attack," by Professor Sir John H. Biles, LL.D., F.R.S.; (2) "Recent Developments of the Hydraulic Transformer," by Herr Professor H. Föttinger; (3) "Shipbuilding Practice of the Present and Future," by Mr. T. G. John; (4) "Some Notes on the Design of Floats for Aeroplanes," by Mr. Gilbert H. Miller. In the afternoon there will be visits to the works of Messrs. Sir W. G. Armstrong, Whitworth and Co., Limited; of Messrs. Swan, Hunter and Wigham Richardson, Limited, and of the Fullagar Engine, Limited. At 9 p.m. there will be a reception at the Assembly Rooms. On Wednesday morning, at 10 a.m., the following papers will be submitted by the North-East Coast Institution of Engineers and Shipbuilders in the Lecture Theatre of the Literary and Philosophical Society:—(1) "Some Notes on Warships Designed and Constructed by Sir W. G. Armstrong, Whitworth and Co., Limited," by Mr. J. R. Perrett; (2) "A Review in the Progress of the Marine Steam Engine on the North-East Coast during the last Fifteen Years," by Mr. A. C. Ross; (3) "Charging of Two-Cycle Engines," by Professor B. Hopkinson, F.R.S., and "A New Type of Internal-Combustion Engine," by Mr. H. F. Fullagar, M.A. In the afternoon there will be visits to the works of the Consett Iron Company, Limited; of the North-Eastern Marine Engineering Company, Limited; of Messrs. R. and W. Hawthorn, Leslie and Co.; of Palmer's Shipbuilding and Iron Company, Limited; and of the Fullagar Engine, Limited. In the evening there will be a reception and dance in Tilley's Rooms. On Thursday no papers will be read. There will be visits to the works of Messrs. Wm. Doxford and Co., Limited; of the Darlington Forge Company, Limited; and of the Fullagar Engine, Limited. In the afternoon there will be a garden party at Lambton Castle. On Friday, at 10 a.m., the following papers will be submitted by the Institution of Engineers and Shipbuilders in Scotland:—(1) "Influence of Varying Temperatures on the Strength and other Properties of Admiralty Gun-Metal," by Professor A. Campion and Professor John G. Longbottom; (2) "The Strength of Welds by the Oxy-Acetylene Process," by Professor A. Campion and Mr. William C. Gray; (3) "Some Experiments on a Diesel Engine," by Mr. W. S. Burns. In the afternoon there will be a garden party at Jesmond Dene, and in the evening a dinner and a reception for ladies.

THE INSTITUTION OF MECHANICAL ENGINEERS.—Tuesday, July 7, to Friday, July 10, the summer meeting will be held in Paris, &c. The following papers will be read and discussed at the meetings if time permits, but not necessarily in the order now given:—"Recent Development of Express Locomotives in France," by Professor Ed. Sauvage; "Compound Articulated Locomotives," by Mr. Anatole Mallet; "Signalling on Trains in Motion upon French Railways," by Messrs. Solacroup, A. Sartiaux, F. Lancrenon, A. Herdner, A. Claveille, and L. Maréchal; "Development of Internal-Combustion Engines for Marine Purposes," by Mr. Peloux; "Balancing of Internal-Combustion Engines," by Mr. H. F. Fullagar; "The New Niclausse High-Duty Marine-Type Boiler," by Mr. J. Niclausse; "Improvements in Motor-Lorries," by Mr. Peloux.—Tuesday, July 7, at 9.30 a.m. Mr. H. Gall, President, and Members of Council of the Société des Ingénieurs Civils, will welcome the Institution in the hall of the Society, 19, Rue Blanche, after which papers will be read and discussed. In the afternoon excursions will be made to various works of interest, and in the evening the Institution dinner will be held at the Hotel Continental at 6.45 p.m.—Wednesday, July 8, at 9.30 a.m., members will assemble in the Hall of the Société des Ingénieurs Civils for the reading and discussion of papers. In the afternoon visits will be paid to works. At 9.30 p.m. a conversazione will be held at the Société des Ingénieurs Civils, guests being received by Mr. and Mrs. Henry Gall and the Members of Council of the Society.—Thursday, July 9, at 3 p.m. A reception will be held in the Bois de Boulogne by Mr. William Hanning, President of the British Chamber of Commerce, and Mrs. Hanning.—Friday, July 10, various alternative excursions have been arranged to works, &c., in Lille, Valenciennes, and Le Havre.

ENGINEERING.

FRIDAY, JULY 3, 1914.

THE SUPERHEATER ELEMENT.

CONSIDERING the extent to which superheating has already been applied, and the decided success which has attended its employment, it is somewhat remarkable that on the one hand the theoretical efficiencies of various types of superheaters have not been more thoroughly discussed, while, on the other, there is not a more extended knowledge of the experimental work which has been carried out, bearing on the economy of superheating generally. Thus we were rather surprised, at the time of Mr. Henry Fowler's valuable paper on "Superheating Steam in Locomotives," being read recently before the Institution of Civil Engineers, to find that it contained a statement to the effect that the author was not aware of any experiments made to show the relative economy of different degrees of superheat. Although reference was made in other parts of the paper to the results of testing-plant investigations, Mr. Fowler appears by some mischance to have overlooked the work done in this connection at Purdue, and several times referred to in our columns, and at the Institution of Mechanical Engineers. The Purdue series of tests was made with superheat of 0 deg., 130 deg., 145 deg., 160 deg., and 230 deg. Fahr., and so far as they went they were fairly satisfactory. They undoubtedly showed an increase in economy with an increase of superheat, and though not as comprehensive as might be wished, owing to the limitations of the Purdue Laboratory, they are quite worthy of record and consideration.

In tests of this character a difficulty at once presents itself. The ultimate economy of a locomotive has to be taken over both the generator and machinery portions combined. Although the engine efficiency is improved with the introduction of superheating, in the most popular method of producing superheated steam there is some reduction in the efficiency of generation. The over-all result is to the good, unless the superheat is low. This disturbance of the efficiency of generation with different degrees of superheat was discussed at some length in ENGINEERING, vol xcii., page 276, and the points then brought out seem generally to have been confirmed by more recent information. Under the circumstances, in any trials with progressive degrees of superheat, the ideal would be to keep the efficiency of generation as nearly uniform as possible and as close as practicable to that of the saturated-steam boiler. For this to be done, only just so much water-heating surface should be removed as is necessary to give place to the superheating surface requisite for the particular superheat aimed at. Unfortunately, this gradual transition is impossible with the commonly-adopted smoke-tube type of superheater. The necessity of having large smoke-tubes, to accommodate the heater elements, sacrifices a certain amount of water-heating surface, whether the elements be designed for high-degree results or low. According to the superheat adopted, therefore, the work taken out of the gases in these large tubes may vary greatly; the waste heat would in some cases be considerable, and there must perforce be an appreciable difference in the proportion of the heat available to the heat utilised under these several conditions.

In the most efficient smoke-tube superheater the element would be so designed that of the heat carried by the gases entering the large tubes the maximum possible amount would be taken up by the steam and water-heating surfaces. At the other limiting extreme we may suppose a superheater formed of such short elements that they hardly enter the smoke-tubes at the smoke-box end. If for water-heating surface the 2-in. or 2¼-in. tube is of good proportions for some typical boiler, a 5-in. water-heating tube would evidently be less efficient, and a larger amount of heat would be conveyed to the smoke-box through these than through the 2-in. tube. This extra heat would be delivered in our limiting case to a small amount of superheating surface; very little would be taken up, and the heat lost would be large, while the superheat would be low.

We therefore conclude that trials conducted with different degrees of superheat, obtained by merely varying the surface of the smoke-tube type of superheater, are far from the ideal, and generally should be regarded more in the nature of an investigation of the possibilities of this particular type of appliance than as conclusive on the subject of superheating, since in other applications this disadvantage might be overcome. Nevertheless, such trials are valuable as bringing out some very interesting points of which notice might be taken in design.

In 1911 we directed attention in these columns to the fact that the double return-bend element, used in the superheaters of the present day, was a comparatively inefficient appliance. We stated that "for a very large part of the superheater surface the transmission is exceedingly low." This we explained in the following terms, which will bear repetition in view of some recent tests carried out on the Pennsylvania Railroad. The words we used were as follows:—"In only two limbs of each element does the steam flow in a direction favourable to absorption—*i.e.*, in a direction contrary to that of the gas; while, again, in only two limbs is the temperature head considerable for any part of the area exposed. The transmission at the ends of the contra-flow limbs must be considerable, especially in the case of the first. It would also be high at the commencement of the second limb, but there the direction of flow is unfavourable, and the rate of transmission must fall rapidly."

To consider what occurs in an element in greater detail, we may follow the course of the steam in the

various limbs. Starting at the smoke-box end, in the case of the first limb the gas and steam are flowing in contrary directions. The temperature difference, though not very large to begin with, rapidly increases as the steam flows towards the fire-box. Transmission throughout this limb is good, and at the fire-box end is high. On turning the corner and flowing back, at first transmission is good owing to the temperature head, but this drops quickly, and the steam is now flowing with the gas; the transfer of heat falls rapidly with an increase of distance from the fire-box. If it does not become negligible after passing out of the hot zone, it certainly is not very material. On again reversing its direction, and flowing towards the fire-box in the third limb of the element, the contrary flow of the hot gas and increasing temperature head are again favourable; but by now the actual difference between the temperature of the steam and gas has been much reduced. Transmission is therefore much smaller than in the first limb, but towards the fire-box end it increases, and is fairly good for some distance in this neighbourhood. On turning the last corner, the steam, now being raised considerably in temperature, receives a little additional heat, but soon passes out of the zone where the temperature head is of useful magnitude, both steam and gas flowing in the same direction. There have been cases, of course, in which the steam in this fourth limb, instead of absorbing additional heat, has, for a good part of the length, actually been supplying heat to the flue gases.

A simple analysis of this kind suffices to show that the useful work is done on the steam in the first limb, part of the second and third, and a very small part of the fourth; the remaining surface would be as well cut out, when a reduction in pipe friction would be secured. In the type of superheater now so popular it is not possible to cut out the last limb, as the steam must be returned to the front end; but there is no sound reason for keeping to the long return bend, of which a considerable portion is valueless. If a little thought and some experimental work had been expended on the subject at first, we think it questionable whether the present form would ever have been adopted. It would not have been very difficult to have fitted up experimentally a tube and element, so as to obtain a record of temperatures at various points of the steam path, but we do not know of anything of this kind having been attempted. Had it been done, the points we have made above would, we believe, have early become apparent. As it is we have had to wait for the substantiation of our views for the conclusion of a lengthy series of tests carried out on the Pennsylvania Railroad testing plant at Altoona, Pa., U.S.A., the results of which have recently been embodied in a paper read by Mr. C. D. Young, Engineer of Tests, P.R.R., before the Franklin Institute, Philadelphia, Pa. While these tests omitted to vary the water surface in proportion to the superheating surface introduced, any other arrangement, as above pointed out, being difficult to make with the smoke-tube system, the point we are now interested in is made abundantly clear. We will consider the results from the point of view of the variation of superheat with the heating surface, for some particular output. Several facts are brought out. In the first place, we find, as might be expected, that a double return bend of the standard pattern, but extending only half-way down the smoke-tube towards the fire-box, produces a lower degree of superheat than a single return bend of equal surface, but extending down the smoke-tube for the full standard length. The advantage of heating surface in the hot zone is thus made evident. The most interesting point, however, is that an element having a surface of only 75 per cent. that of the standard produced a degree of superheat greater in the proportion of 10 : 9 than that of the complete standard double-return bend.

This 75 per cent. element was of the usual doubled hair-pin type, but with the doubling only extending half way back from the fire-box end towards the smoke-box. The inefficient portion towards the smoke-box end was abolished with the benefit cited. The factors entering into the question are the two temperatures, the speed of the steam and gas, and pipe friction. By cutting out unnecessary length friction is reduced, and the velocity of the steam increased, both tending to better results. Even an element which possessed only 62½ per cent. of the standard element surface, with the doubling extending but a quarter of the usual distance back, gave a degree of superheat which was practically eight-ninths of that given by the standard element. Compared with a single-bend element, an addition of 25 per cent. of surface in the form of a short doubling at the fire-box end increases the superheat 41.6 per cent. An addition of 50 per cent. in the surface, in the form of a return bend, increases the superheat 78.1 per cent. If the return bend is further prolonged to the standard length, the superheat is less than in the last case.

We must confess that there appears to be a little inconsistency in the results recorded for some of the other elements tested, but the point which we think is made quite clear is the high value of the surface at the fire-box end, and the little use of that towards the smoke-box end in three out of the four limbs if high temperatures are aimed at. The endeavour should be to concentrate the heating surface in the most effective zone, so as to keep the total length, and consequently pipe friction and pressure drop, as small as possible. Even with the degrees at present worked to it would appear advantageous to abolish the unnecessary material, weight, and pipe friction; while if, as Mr. Stenning recently suggested, the future will see much higher temperatures aimed at, it would seem that greater attention must be given to these points.

It is impossible in the present smoke-tube system to get rid of the last limb leading the steam back to the smoke-box, but the present useful, or even additional, heating surface might be concentrated in the hot zone in the form of an open cork-screw spiral at the fire-box end of the first limb, the single return member running back from the end nearest the fire-box through its centre. If such an arrangement gave a higher resistance to the flow of the gases, it might necessitate some alteration in drafting at the front end, but this could be easily tested. It might prove feasible to develop some form of sheathing to protect the return limb, to prevent it giving up heat to the gases. There would only be one abrupt change of direction for the steam in such an element instead of the present three.

The tests generally point to the desirability of evolving, if possible, something different from the present smoke-tube element. It may ultimately prove possible to break away from this with advantage. The ideal would be to superheat wholly in a hot zone, as is done in some systems nowadays in marine and stationary practice, and to lead the steam off from this to the cylinders, protecting it on the way. It would reflect greater credit on the present generation if more attention were devoted to this question. It is rather disappointing that practically all the superheater designs adopted on any scale have slavishly followed the return-bend and smoke-tube principle, the distinctive features being some special pattern of headers, pipe-joints, and other matters of application, rather than of principle. It does not say much for the logic of rules which, in proportioning water to steam heating-surface, provide about 25 per cent. too much of the latter, and that of no value. What can be said, too, for those methods which interpret superheater surface as "equivalent" water-heating surface? If part of the surface does no work, it cannot be equivalent to the worst-placed water-heating surface, which even at the tube ends is of some value, owing to the temperature difference between the gases and water still being appreciable. Empirical rules of this kind can only be allowable if it is recognised that they are limited to one type of application, and not to superheating in general, a proviso commonly overlooked.

FURTHER HYDRO-ELECTRIC POWER UNDERTAKINGS IN NORWAY.

THE list of large industrial ventures based upon a continued exploitation of Norway's water-power is steadily increasing. Thus a large power-station with a capacity of some 50,000 horse-power is being laid out at the Folla River, an auxiliary to the Surna, in the Surendale. It will be necessary to construct a tunnel 3 km. long through the Sande mountain, whereby a satisfactory fall will be obtained. In its present state the Folla is of no special moment, but by means of damming, tunnelling, &c., a capacity of 50,000 horse-power for the new power-station is reckoned upon. The station will be located at a place with good harbour accommodation and sites for new industries. In the absence of a natural reservoir it will be necessary to construct a dam across a flat valley, between the steep mountains of the Troldheimen, and the wall across the Folla Valley is to be 20 metres high. This large undertaking is controlled by the owner of the water-power of the Heane River, in the Southern Drontheim district, which, duly exploited, will represent some 15,000 horse-power, and this, it is understood, will be applied to electric ore-smelting. At Folla there are large deposits of limestone, which have been secured.

The building of another hydro-electric power-station has just been decided upon, the cost of exploitation and transmission amounting to about 195,000*l*. The power will be derived from the Högfos Falls, and will amount to some 25,000 horse-power, which is to be transmitted to the town of Risör, a distance of some thirty miles. The fact that the power can be utilised in an existing town, instead of works and dwellings having to be built in an entirely desolate country, as is the case with so many large power-stations, means a very material saving. The Akershus district has just purchased the Raanaasfos Fall; the price for the waterfall is 55,000*l*.

The Arendal Water-Power Company, which is already in operation, is to be greatly extended, at an outlay of some 240,000*l*., and the Bjölvo waterfall is to be exploited.

A Norwegian journal of some standing has recently given expression to some apprehension as regards an over-production of hydro-electric power-stations, more especially as far as the electro-chemical industry is concerned. Only a few years ago it was difficult to find uses for capacities of 5000 to 10,000 horse-power in this industry, but such capacities no longer count for anything. Now the installations and projected schemes comprise capacities of 50,000, 100,000, or even several hundred thousand horse-power, in Norway, Italy, Spain, Savoy, Canada, and even in Iceland. As far as Norway goes, not only are the installations already in operation at Rjukan, Tysse, Arendal, &c., being extended, and that on a large scale, but schemes are being advanced at Sande, Matre, Tyin, Aura, Take, Lysefjord, Bölve, Höjangen, Osa, Glomfjord, &c. If, say, only half of the projects just enumerated are completed within the first few years, the question presents itself as to what shall all this power be applied?

It is a well-known fact that the old, or original, electro-chemical products, aluminium, carbide, ferro-alloys, all have very limited areas of consumption, which no doubt grow every year, but even a small over-production leads immediately to a decline of prices and to crises. Such have already arisen twice during the comparatively short span of fifteen to twenty years which has passed since these manufactures commenced, and experts are already prophesying a third crisis, with ruinous prices below the cost of production, as being near at hand. It will be remembered that during the former crisis at least two Norwegian carbide manufactories had to stop; the losses were heavy, as the factories had to be sold for a song.

On the other hand, the opinion is often expressed that the new electro-technical nitrogen industries—artificial manures—have an unlimited scope for the sale of their products. But this view must assuredly be accepted with considerable reserve. On the market for artificial manures the consequences of over-production are already felt. The quotation for Chili saltpetre has dropped from 10.50 marks in the beginning of March to 9.55 marks in the beginning of May, the market having been unable to receive the offered quantities of Chili saltpetre and artificial manures. Nor does the position of sulphate of ammonia offer any encouragement, as German reports show. Also the demand for cyanide shows signs of falling off.

In addition to all this, new methods have been discovered by which nitrogenic manures can be manufactured chemically, without the aid of electricity (as, for instance, the Haber system), so there seems every reason not to embark too lightheartedly on wholesale exploitation of water-power.

THE ROYAL AGRICULTURAL SOCIETY'S SHOW.

THE Royal Agricultural Society's Show, which this year is being held at Shrewsbury, opened on Tuesday last. This is the third time in the history of the Society that the Show has been held at this

centre. The weather, which means so much for the success of an exhibition of this character, has been propitious, and in many respects the Show has proved an immense success. Only on one occasion has the prize fund been larger than it is this year, while the entries in the live-stock classes are 500 in excess of those of Bristol, last year, and, of course, far ahead of those of the previous Shrewsbury Shows of 1845 and 1884. The implement classes, with which we are more concerned, do not cover the same extent of ground as they did last year at Bristol, nor is the number of stands as great, but the exhibits themselves show no sign of becoming less interesting, and quite a number of new appliances are entered for the Society's Silver Medal.

FIG. 1. THE STOCK MOTOR-PLOUGH; THE STOCK MOTOR-PLOUGH COMPANY, BERLIN.

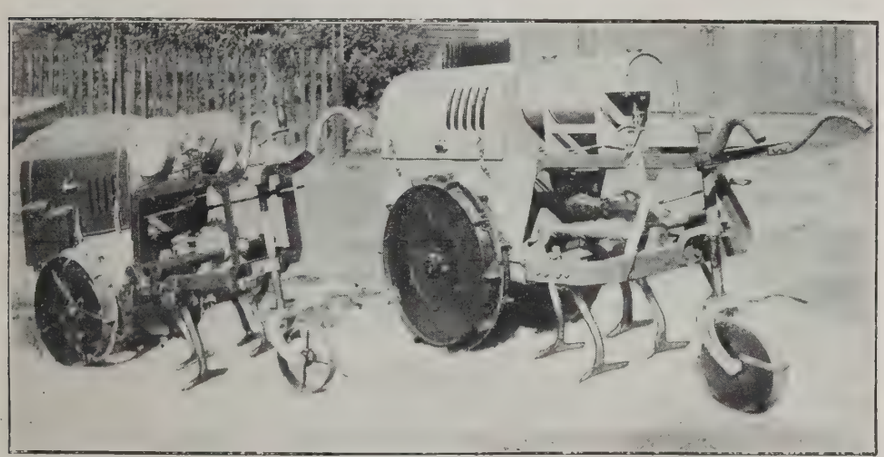

FIG. 2. THE IVEL-BAUCHE MOTOR-HOES; THE IVEL AGRICULTURAL MOTORS, LTD., BIGGLESWADE.

INTERNAL-COMBUSTION ENGINES.

A noticeable feature in this part of the Show is the large number of petrol and semi-Diesel engines of comparatively small capacity, suitable for driving farm machines, &c., and also the number of motors fitted up as portable engines, or actually applied to farm implements.

There are, for instance, several new motor-ploughs. Among them is a large six-furrow plough manufactured by the Stock Motor-Plough Company, of Berlin, whose business in this country is conducted by Messrs. F. W. Moellenkamp and Co., 85, Farringdon-street, E.C. This plough we illustrate in Fig. 1 herewith. This machine has two wheels 7 ft. 3 in. in diameter, with a trailing steering-wheel. The large wheels can be widened for working on very wet land, and various types of grips are fitted to the rims according to the land worked. The weight of the machine is 5½ tons. It has proved very successful on wet soil in the neighbourhood of Boston, Lincs. A single framing runs from back to front of the machine, the motor—a four-cylinder water-cooled petrol engine of 50-55 horse-power—being carried at the front end. Although the machine is large, it is arranged for one-man control from the driver's seat. The shares are raised or lowered by a crank-handle near the seat working a pinion-and-rack mounting for the trailing wheel. A dial near the driver's seat indicates the depth to which the shares are set. This operation can be performed by hand or by power. The drive is by gear throughout, the engine running at 720 revolutions per minute on benzol. There are four forward speeds and two reverse, the speeds ranging from 2½ to 4 miles per hour, according to the land being ploughed. The machine has a fuel-tank of 25 gallons capacity, with a smaller tank for a lighter petrol spirit for starting up. Bosch ignition is fitted, and to facilitate starting there is a compression release lever. The oiling is by the forced lubrication on the Bosch system.

Another motor-plough with several distinctive features is one exhibited by Messrs. Bumsted and Chandler, Limited, Hednesford, Staffordshire. This machine is also a one-man appliance. It is styled the "Ideal," and, in addition to ploughing, can be made to work as a self-contained cultivator, as a tractor, or as a portable plant for driving purposes. As a tractor it has taken a load of 6 tons at 6 miles per hour up a slope of 1 in 10. In this machine the motor is mounted as a four-wheeled tractor, with the plough fitted as an extension-frame at the rear. The model shown had four shares. The engine, of 35 horse-power, is of the four-cylinder type. The fuel-tank capacity is 35 gallons. The machine is provided practically with motor-car control, there being two forward speeds of 3 and 6 miles and one reverse of 3 miles per hour. From the second-motion shaft power can be transmitted from the driver's seat through the free differential gear, or through the locked differential so that the road-wheels cannot rotate independently, or to one or the other road-wheel alone. Foot-brakes are fitted on the differential shafts, and hand-brakes on to the inside of the rims of the back wheels. There is a winding-drum capable of taking 30 yards of steel cable; this can be operated in either direction when the tractor is either moving or stationary. The large wheels are 5 ft. 6 in. in diameter by 10 in. wide. They are fitted with an interesting arrangement of spuds, cam-operated and self-cleaning. These spuds are of ⊏ section, except where they pass through the wheel rim, where they are given extra width by being turned into spuds of F-shaped section. They are pushed out by a steel ring mounted on a large roller-frame bearing encircling the axle, and mounted so that each spud is pushed out as it approaches the ground, and is free to be drawn in by a stiff spring on leaving the soil, thus cleaning itself, and not projecting in the upper portion of the path of the periphery. The projection given to these spuds can be varied from 0 in. to 4 in. by a screw and spanner from the driver's platform. The front axle is of the swivelling pattern, with centre springing, the front springs being 3 ft. long. The back springs are 3 ft. 6 in. long.

The plough consists of ⊏-section frame, more or less of the shape of a parallelogram, with several cross-bars. The shares are mounted on these cross-bars, and can be easily adjusted on them to give any particular width of furrow from 9 in. to 12 in. wide. The plough frame can be adjusted vertically so as to cut furrows 4 in. to 8 in. deep, the draught being through oblique rods attached low down to the motor, and brought up to the plough-frame at the back of the first share, in such a manner as to pull the back three down into the ground. The plough at the end of the furrow is lifted by a crane arrangement consisting of a double-crank axle with two chains attached to the cranks, one being led to the front end of the plough-frame and one to the back. The two cranks are about 100 deg. apart, so that a certain lag is allowed to the back end. The front share is therefore lifted first, and the back end is not raised until the last share has reached the same point.

Of the smaller class of motor appliances we may instance two Ivel-Bauche motor-hoes. These are being shown by the Ivel Agricultural Motors, Limited, of Biggleswade, Bedfordshire. They are actually French machines, and are of two sizes, of 2¾ and 4 horse-power respectively, and both of these we illustrate in Fig. 2, annexed. The machines are extremely handy in movement, and they are suitable for hoeing orchards, vineyards, and plantations. The models are much the same except for the size of engine, the smaller type having an engine 90 mm. by 100 mm., and the larger one 100 mm. by 100 mm. The engine is air-cooled by a little belt-driven fan,

forcing air into a casing which fits round the cylinder after the manner of a water-jacket, but with a large outlet at the back to admit of the current of air escaping. In this way the air is brought into close contact with the cylinder, instead of being to a large extent wasted. The depth of hoeing can be regulated by a trailing wheel. The hoes are mounted on two transverse rocking-shafts worked by a toggle-gear drive from the main shaft, so that a rapid-hoeing motion is given to each blade while the machine itself travels forward. The hoeing motion and the forward travel have independent controls, so that the machine can be moved from place to place with the hoes out of gear. The small pattern (S) will travel between plants set not less than 25 in. apart, and the large (L) between rows 49½ in. apart. This machine has met with considerable success in France. The Ivel Company are also exhibiting, it may be added, two of their regular agricultural motors which are now so well known.

Among the exhibitors of agricultural motors are also included Messrs. Saunderson and Mills, Ltd., of Elstow Works, Bedford. This firm has reduced its types to four standard patterns, and the success of their work may be gauged by the fact that they have increased the output of their works 400 per cent. in three years. The sizes of tractors now built by them are of about 10, 20, 30 and 45 brake horse-power. The latest model of the 10-horse-power size, known as the "Little Universal," is illustrated herewith in Fig. 3. The feature of this machine is that, with some little alteration to the pole, ordinary horse ploughs, &c., can be employed with it. The engine is a single-cylinder, 5½-in. by 8-in. paraffin motor, starting on petrol, with control for the carburettor and vaporiser suited for working with different oils in different countries. The heat taken from the exhaust to the vaporiser can be easily varied, so that good results can be obtained under a wide range of conditions. The change over from one fuel to the other, with the necessary carburettor and vaporiser adjustments, are effected instantaneously. The engine base and the base of the transmission gear-box are a single casting. Three forward speeds of 2, 3, and 5 miles per hour are provided, and one reverse. The machine weighs about 30 cwt., and is only 4 ft. 1½ in. wide. The controls are all near the driver's seat. In this pattern of motor, when fitted with a plough or other implement behind, the whole implement, &c., wheels and all, is lifted bodily off the ground at the end of the furrow, instead of the shares being raised on the wheels. The machine has a draw-bar pull of 1500 lb. It has belt-pulley and a winding-drum on the rear axle; the differential gear has a movable pin-lock. Ignition is by magneto, and lubrication by a geared pump. The firm are also showing their standard patterns in the larger sizes, but only the small machine is entered for the Silver Medal.

The Daimler Company are showing four machines altogether, two of them being lorries, one of the "Colonial" 5-ton type, and the other a light 2-ton machine. The chief feature of interest in the former, which has a 50-horse-power engine, is the new winding-gear with which it is fitted. The gear is powerful enough to lift the machine, and should therefore prove a valuable addition for colonial work. The smaller lorry is of the Daimler Company's well-known standard design. The other two exhibits of this firm are two tractors, one of 50 horse-power and one of 105 horse-power. The former has a four-cylinder water-cooled sleeve-valve engine of 120 mm. bore and 160 mm. stroke. The driving-wheels are 6 ft. in diameter and of 12-in. to 18-in. face. The usual cone clutch and enclosed gear-box are fitted, giving two forward speeds and one reverse, of 5 and 2½ and 2½ miles per hour respectively. The draw-bar pull amounts to 4000 lb. The cooler is arranged in a large rectangular tank. It is composed of a series of thin sheet-metal sections or boxes, with about ¼-in. water space between the two large sides, the edges being made tight with ordinary tinsmith-type joints. The large side sheets have bosses pressed on them at regular intervals, so as to keep the various compartments spaced apart. Some of the bosses have holes, matching holes in the neighbouring section, the joints between the two being made by rubber rings, and the whole lot of sections being drawn up tight. No fan is provided, the current of air through the cooler being induced by the engine exhaust, which is carried into a chimney placed above the cooler.

The larger tractor exhibited by the same firm is primarily intended for work abroad. It has wheels 8 ft. in diameter by 2 ft. 9 in. face, and a six-cylinder engine. It has, in addition, a small donkey engine for starting up the main engine. This machine, which has a draw-bar pull of 12,000 lb., is, of course, of large size, weighing 12 tons, and is only intended for work on an extensive scale. The smaller machine is intended for more general use, such as would serve ordinary purposes in this country. Indeed, it is a noticeable feature of the Show that the smaller farmer is receiving more attention than formerly, several makers catering for this class of farmers, who, if they could replace their horse implements by motor machines at a reasonable cost, would not hesitate to do so, but do not like to expend much money on an expensive machine which must stand idle for a large part of its time.

There are a large number of firms showing lorries and motor vehicles of one type and another. Among these the Leyland Motors, Limited, Leyland, Preston, have a heavy petrol brewer's lorry and a motor char-a-banc for twenty-seven passengers. This vehicle secured the War Office subsidy, the char-a-banc bodies being interchangeable with a platform for aeroplane work. It weighs 2½ tons, and has a 30-horse-power engine. Another exhibit of this firm is a motor fire-engine fitted with a Rees-Roturbo pump. This machine has speeds up to 50 miles per hour, the engine being one of 60 horse-power. Messrs. Leylands recently received orders for twenty-four motor fire-engines for London, which, with eight already working there, makes the largest order yet given for this type of machine. Although Messrs. Leylands have taken up motor-lorry work, they are turning out to-day more steam-lorries than they did before they started building the later type of machine. In Fig. 4 we illustrate one of the uses to which their standard steam chassis has been put. This machine is a vacuum tank for cesspits or gullies. The tank is of 1000 gallons capacity. The chassis is fitted with the tipping gear-drive, which, however, is adapted to work a screw conveyor open in the bottom of the tank, and used to force any solid matter towards the back end, where it is sent out through a 12-in. manhole. A vacuum is produced in the machine by a steam-ejector. When this is formed the suction-pipe is let down into the cesspit or gully by means of a crane on the side of the tank. The cock is then opened, and the tank will fill in 4 minutes. A top man-hole, 15 in. in diameter, is fitted. The whole weighs about 12 tons gross (with the tank full). The machine is

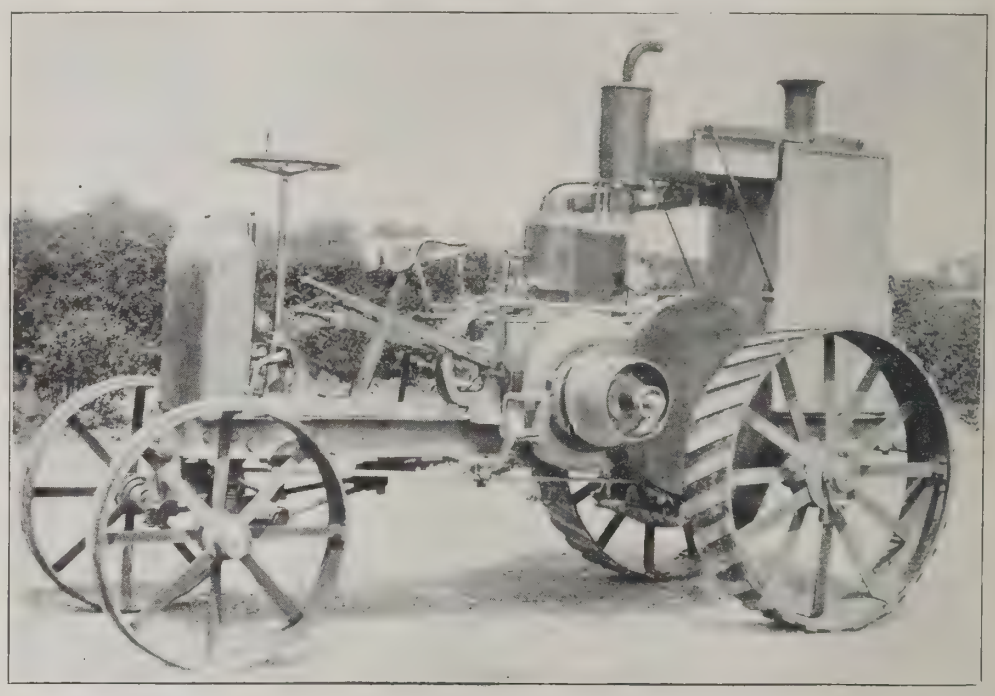

FIG. 3. "LITTLE UNIVERSAL" MOTOR; MESSRS. SAUNDERSON AND MILLS, LIMITED, ELSTOW WORKS, BEDFORD.

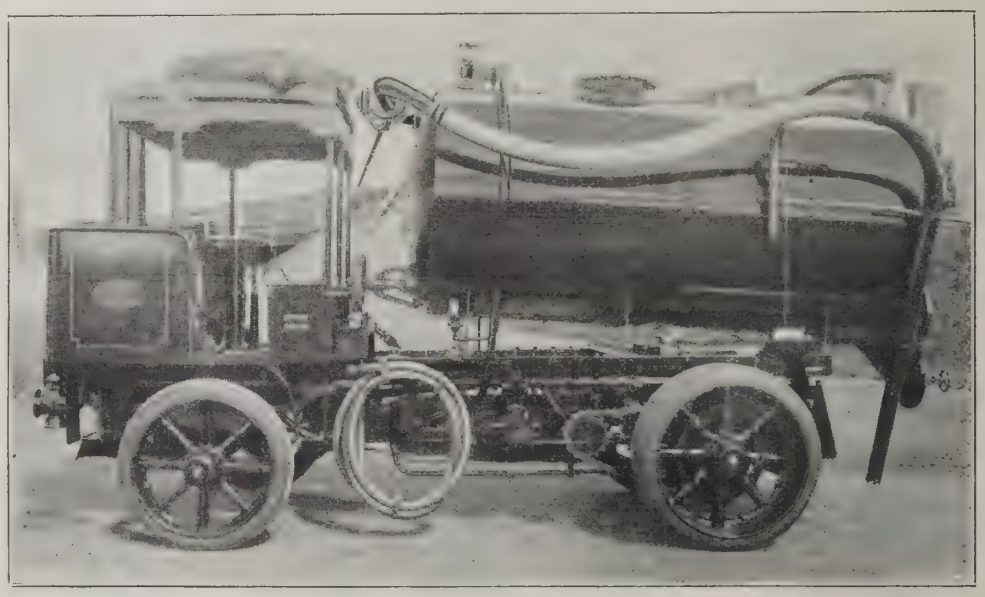

FIG. 4. VACUUM GULLY-EXHAUSTER; THE LEYLAND MOTORS, LIMITED, LEYLAND, LANCASHIRE.

fitted with rubber tyres, and has a speed of 8 miles per hour. The one on exhibition is one of two on order for Nottingham, others having been supplied to Kensington, Chelsea, Bombay, Calcutta, &c.

Among the smaller oil-engines Messrs. Martin's Cultivator Company, Stamford, are showing a new design of crude-oil engine, which we hope to refer to at greater length on a subsequent occasion. These engines are of the semi-Diesel type, two sizes, the 8-10 and the 25-horse-power engines being single cylinders, and the third a twin-cylinder engine developing 20 horse-power. They are two-cycle engines embodying several features, a description of which we shall defer for the present.

Messrs. Blackstone and Co., Limited, are exhibiting a large number of oil-engines, making a special show of their small vertical type. These engines are four-stroke cycle and of very neat appearance, being also very compact. The engine is also mounted as a portable type, of which form we give an illustration in Fig. 5 herewith. In this pattern the engine is mounted on a girder

FIG. 5. PORTABLE OIL-ENGINE; MESSRS. BLACKSTONE AND CO., LIMITED, STAMFORD.

carriage borne by four wheels. A novel feature is the circulating arrangement, which is shown in the diagram, Fig. 6. The circulating pump is dispensed with, and its place taken by a device utilising the impulses of the exhaust. Water flows by gravity from the tank to the chamber A through the non-return valve C. The exhaust pressure also has access to this chamber by way of the pipe B, and the water is driven out past the valve E into the air-chamber D. From thence it passes to the cylinder along the pipe H. The valve E is provided with spring adjustment, so as to regulate the pressure at which it will open. From the cylinder the water passes to the top of a tall cooler, made of a cone of perforated metal, down which it flows into the tank, being brought on the way, of course, into contact with a large quantity of air. The other exhibits of this firm include a 75-brake-horse-power crude-oil engine working with a compression pressure of 150 lb., and fuel-injection air at a pressure of 400 lb.

Messrs. Robey and Co., Limited, Lincoln, are also exhibiting several oil-engines of the semi-Diesel type. These engines are of the two-cycle type, compressing in the crank-chamber. The sizes shown are of 6 and 8 brake horse-power, and two of a larger pattern—one being of 25 horse-power, and the other of 12 horse-power—are mounted as portables. The engines are of the valveless type, and govern on the supply oil; they are started with a lamp. They are very neat in outward appearance.

Among the exhibits of Messrs. Marshall, Sons and Co., Limited, Gainsborough, are two crude-oil engines. These we illustrate in Figs. 7 and 8, page 22, the first showing a 6-brake-horse-power fixed semi-Diesel engine, and the other a portable 16-brake-horse-power engine on the same principle. The former runs at 400 revolutions per minute. It is of the two-cycle type, the rating being the maximum for crude oils and residuals, or the working output for refined oils. There are no air or exhaust-valves in the cylinder-head, and the engine is in consequence very simple. The compression pressure is about 175 lb. per sq. in., which is not high enough to make starting difficult. With good crude oil a consumption of 0.5 pint per brake-horse-power hour is obtained. The governor of the high-speed spring-loaded type regulates the stroke of the fuel-pump. Ample arrangements are made facilitating cleaning of the water-jacketed spaces round the vaporiser head and cylinder. Air for the cylinder is compressed in the crank-case. In Fig. 8 the 16-brake-horse-power portable engine is shown. It is similar in principle to the preceding, but modified, so as to be mounted on a mild-steel girder-frame carried by four wheels. This engine runs at 330 revolutions per minute. The cylinder in this pattern is cooled by water circulated by a centrifugal pump drawing water from a tank under the frame. The pump is always flooded. From the cylinder-jacket the water passes to a cooler, where it falls down over a series of wooden frames, a current of air being induced up through the cooler by the exhaust, which is admitted to a stack above the cooler. The exhaust which is led to this stack previously passes through a silencer in front of the frame, another being arranged at the top of the water-cooler. The fuel-tank is bolted to the silencer on the frame, and in cold weather the fuel is thus kept at a sufficiently high temperature. This engine is fitted with a compressed-air bottle for starting. This bottle is in connection with the cylinder, and can be charged with a pressure of about 150 lb. per sq. in. while the engine is running. The arrangement serves its purpose admirably.

The National Gas-Engine Company, Limited, Ashton-under-Lyne, are exhibiting several engines using heavy crude oils. There are four-cycle engines, with mechanical pulverisers for breaking up the fuel. This pulveriser consists of a valve loaded by a powerful spring, lifted at the end of each stroke of the fuel-pump. The oil passes through a spiral and is broken up into a fine mist, and then passes into hot compressed air, causing partial vaporisation, this process being completed in the vaporiser. The temperature of compression is sufficient to keep the engine going after starting with a lamp. The oil-pump is driven by a quick-acting cam off a cam-shaft. A separate band enables it to be worked by hand or thrown out of gear. The governor is gear-driven, and controls the supply of fuel to the cylinder.

On their gas-engines, some of which are also exhibited, the National Gas Engine Company are introducing a new type of variable admission governing gear. This we illustrate in Fig. 9, on page 22. The inlet-valve is worked by cam-gear by two levers. The motion of one lever is transmitted to the other by means of a movable plate,

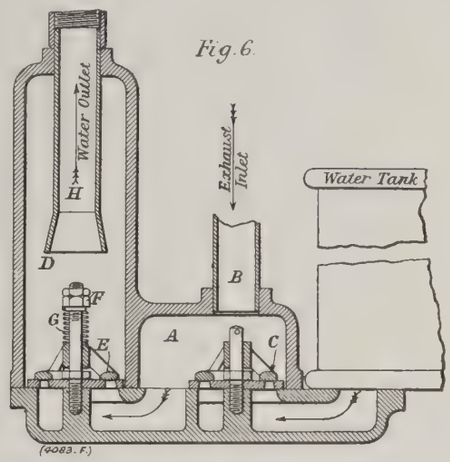

FIG. 6. EXHAUST-DRIVEN WATER-CIRCULATOR FOR COOLING WATER.

the level of which is controlled by the governor. As the speed rises this plate is raised, and the valve-opening is diminished. If the plate falls, the valve-opening diminishes. The inlet-valve is contained in a casting fixed to the back of the cylinder by bolts, and is easily removed without disturbing the valve-gear.

This firm have also a new pattern of bituminous producer-gas plants, of capacity suitable for 120-brake-horse-power engine plant. In this plant the generator has a water-sealed bottom and a conical fire-grate. The water-seal hermetically seals the plant, and provides an easy means of removing clinker. Clinker adhering to the sides of the brickwork can also be removed through poke-holes, &c. From the generator the gas is taken through a large pipe to a scrubber, in which is fitted a feed-water heater. The wet scrubber is fitted with wooden grids, and after passing through these the gas goes through a rotary tar-extractor to a dry scrubber filled with coke and wood-wool. The scrubbers are of thick steel plates, the wet one having a cast-iron base.

The Campbell Gas Engine Company, Limited, Halifax, have several of their standard engines on exhibition. Among them is a two-cylinder vertical marine oil-engine, of 30 brake horse-power, of the hot-bulb crude-oil type, but fitted with an interesting type of reversing gear. With this gear the engine is first slowed down until a pre-ignition may be given. This is arranged for by a block working in a groove and altering the timing of the pump for the fuel injection. When one pre-ignition has taken place, a friction arrangement drags the block back to the normal end of the slot and the pump is then actuated as usual, the engine continuing to run in the reversed direction. In addition to a suction-gas plant, horizontal gas-engine and other types, the Campbell Company have working an 18-brake-horse-power horizontal crude-oil engine of the semi-Diesel type, but of sufficiently high compression (250 lb.) to start up from the cold without using a lamp. This engine has variable governing, regulated by a vertical wedge-block, the position of which is regulated by the governor. This block is interposed between the striker and

the pump-plunger, the stroke of which is altered by the thickness of the wedge in line.

Messrs. Petters, Limited, of Yeovil, are also one of the firms adopting this principle of a wedge directly operated by the governor on their semi-Diesel crude-oil engines. The firm is showing a 50-horse-power single-cylinder engine of this type, as well as others of this class, and, in addition, several examples of a small horizontal engine fitted with magneto ignition. This engine is started on petrol, and then changed over to paraffin. The governing adopted in the case of Messrs. Clayton and Shuttleworth's horizontal oil-engines of the semi-Diesel valveless type consists in raising or lowering, by means of a lever worked by the governor, a rod driving the pump so that it comes into contact with a striking-lever at different distances from the latter's pivot. The striking-lever is moved to and fro by a push-rod worked by a cam on the main shaft. This firm have several engines of this type at work, ranging from 7½ brake horse-power upwards.

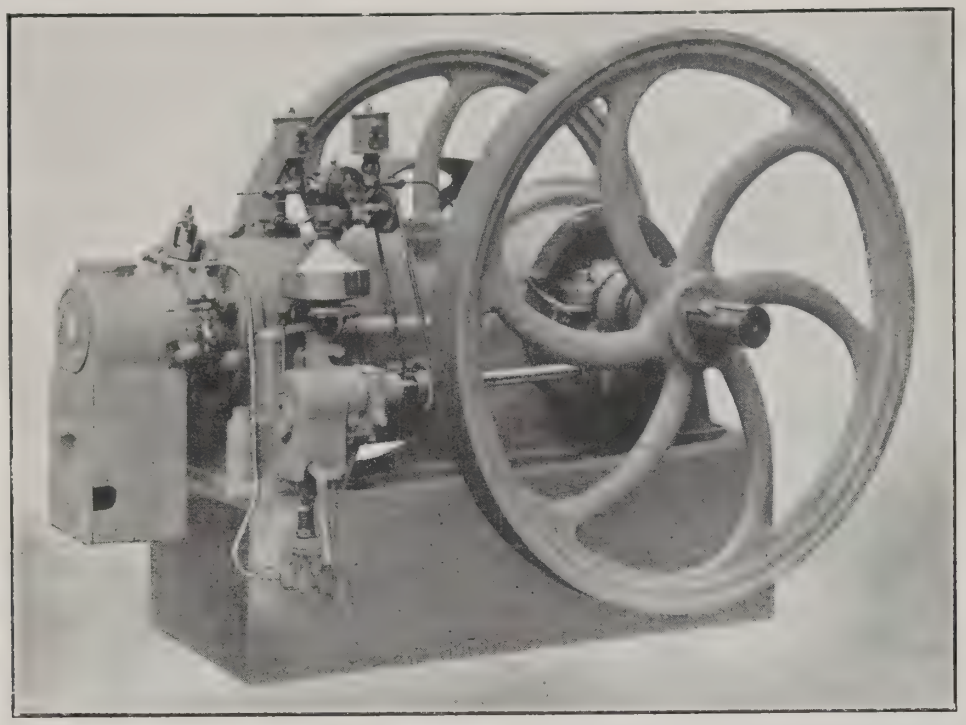

FIG. 7. 6-HORSE-POWER SEMI-DIESEL ENGINE; MESSRS. MARSHALL, SONS AND CO., LIMITED, GAINSBOROUGH.

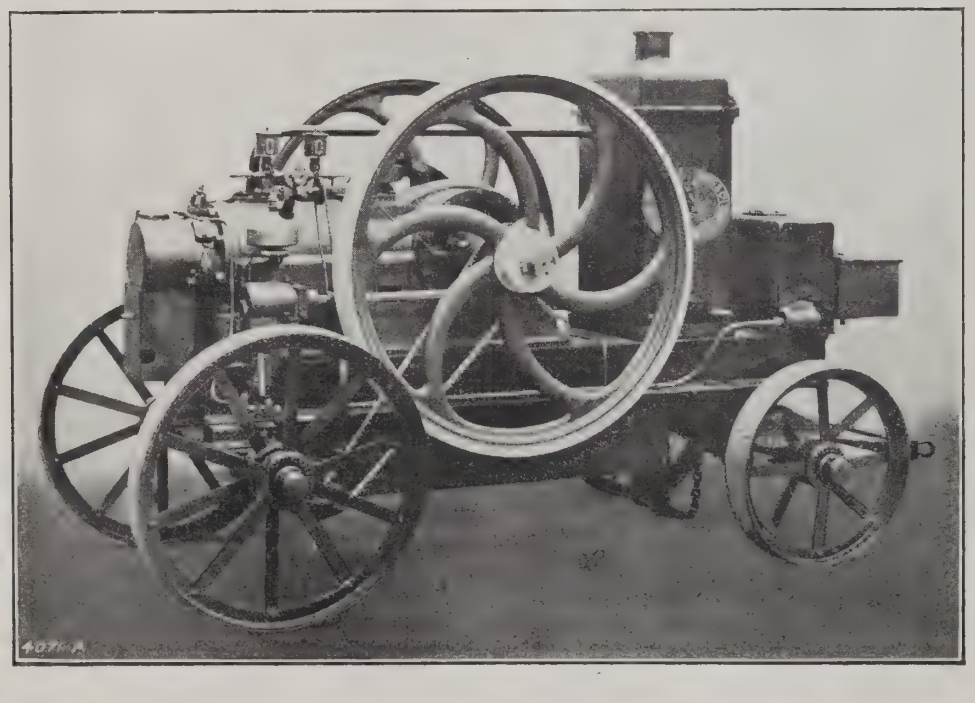

FIG. 8. 16-HORSE-POWER PORTABLE SEMI-DIESEL ENGINE; MESSRS. MARSHALL, SONS AND CO., LIMITED, GAINSBOROUGH.

The exhibit of Messrs. Crossley Brothers, Limited, Openshaw, includes several of their standard types of engines. A standard suction-gas plant with open-hearth grate is at work; this was illustrated by us in ENGINEERING, vol. xcvi., pages 19 and 776. Messrs. Crossley's latest type of gas-engine with variable governing was described in ENGINEERING, vol. xciv., pages 15 and 726.

It is impossible, of course, to mention the particular features of all the internal-combustion engine exhibits. The number of small and cheap engines working is quite astonishing. Judging from the stands, there must be an enormous demand for little engines on movable stands or trucks, but competition does not appear to have a very good influence on the quality of article produced. This is more or less inevitable, but the contrast between the finish of some of these small engines and others is very marked. If the price be low and the engine will work reliably, it will, of course, prove attractive to many, and there are innumerable uses to which quite small units can be put about a farm. A fairly common feature of these engines is the hopper cooling, doing away with the ordinary circulation and tank, and by simplifying the engine, permitting a reduction in price.

STEAM-ENGINES.

Numerous firms, as usual, exhibited steam-tractors and agricultural engines. Among these were to be found Messrs. Marshall, Sons and Co., Limited, of Gainsborough, whose oil-engine exhibits are noticed above. Messrs. John Fowler and Co. (Leeds), Limited, also show numerous engines of this type, including a 14-horse-power ploughing-engine, a 6-horse-power traction-engine, a 7-horse-power road locomotive, and other machines. Messrs. Fowler also show an example of the Fowler-Wyles double-furrow motor-plough. This we described when it was exhibited at the Show of last year. One of the most interesting of Messrs. Fowler's exhibits was a 10-ton steam road-roller fitted with a tar-sprayer and road-sweeping brush. The tar is contained in a tank under the boiler-barrel, and of a capacity of 160 gallons. Above the tank, on the left-hand side of the machine, is a rotary pump. This pump is fitted with piping arranged so that, with a tumbler cock turned one way, tar will be drawn up through a suction-pipe and delivered to the tank. With the same cock thrown over another way, the pump will draw from and deliver into the same tank in order to mix the tar, when this should be advisable. The tank is provided with about 60 ft. of pipe surface, through which either live steam or exhaust steam from the cylinders may be led, for the purpose of warming up the tar before it is passed to the sprayer. The tar is delivered at a pressure of 300 lb. per sq. in. to six jets pointing downwards on a transverse pipe at the back of the engine. A flexible pipe and attachment is furnished, so that the footpaths may be tarred at the same time. In use, a road is first swept clean and then tarred, or the system may be used for grouting new metal. The engine will do in five minutes a length of 300 yards, which is said to be as much as a day's work for an ordinary spraying-machine. The engine itself is a compound, fitted with two speeds and the usual appliances. We hope to illustrate this arrangement in a future issue. The other engines exhibited by Messrs. Fowler were practically their standard types, in which practice has shown very little alteration to be possible in the direction of adapting them better to their work.

Messrs. Robey and Co., Limited, of Lincoln, are exhibiting a 100-horse-power uniflow engine with a locomotive boiler. This engine is on the Stumpf system, on which Messrs. Robey have now built engines for some years. This large engine has the regular Stumpf valve-gear, but a cylinder is

Fig. 9.

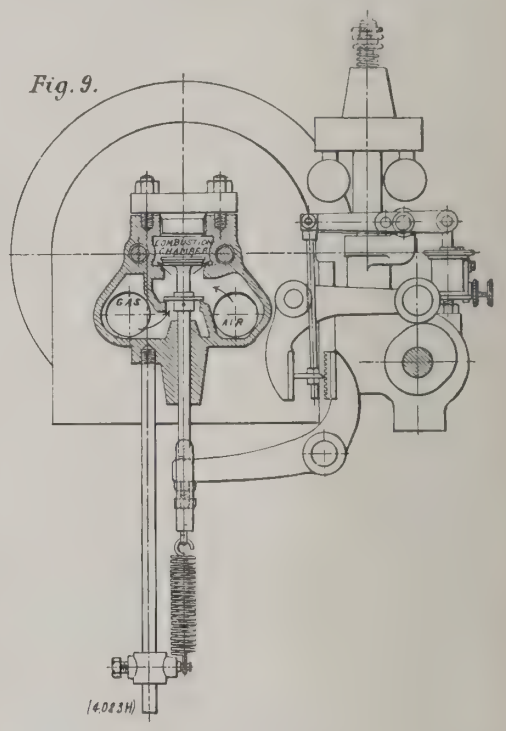

FIG. 9. GAS-ENGINE GOVERNOR-GEAR; THE NATIONAL GAS-ENGINE COMPANY, LIMITED, ASHTON-UNDER-LYNE.

also exhibited in which the uniflow system is adopted in combination with a special form of Messrs. Robey's gear. The boiler is fitted with a superheater in the smoke-box.

Several firms are showing superheaters applied to locomotive-type boilers. For instance, Messrs. Davey, Paxman and Co., Limited, Colchester, who are showing a 32-brake-horse-power gas-engine and suction-gas plant, have also 6 and 7-horse-power traction-engines and a 10-horse-power compound portable engine, of which we give illustrations in Figs. 10, 11, and 12, herewith. This engine has cylinders 6½ in. and 10½ in. in diameter, with 12 in. stroke, running at 180 revolutions per minute. The boiler pressure carried is 160 lb. The superheater is arranged in the smoke-box and gives about 100 deg. to 120 deg. of superheat. The superheater consists of a series of bent tubes, arranged at a level above the flue tubes, so that it does not interfere with the cleaning or repair of the latter. The smoke-box is provided with a double-damper arrangement. These dampers are shown at E and F in Fig. 11, and they are worked simultaneously. When E is in the vertical position and F horizontal, the gases from the flue-tubes pass over the superheater surface. When E is horizontal and F vertical they are by-passed straight to the chimney. This is an advantage when raising steam. The steam enters the superheater at A, and leaves, superheated, at B. Baffle-plates C and D ensure the gases passing over the tube surface. A three-flow tubular feed-water heater is also fitted on this engine, which will develop four times its nominal horse-power at a consumption, we are informed, of less than 2 lb. of coal per brake horse-power. Messrs. Davey, Paxman's other engine exhibits are also powerful machines. The nominal brake horse-power traction engine has a cylinder 8 in. by 12 in. and working pressure of 160 lb., the horse-power developed being 30. This engine has two road speeds, compensating motion, slip-winding drum, and 50 yards of steel cable. The 7½-horse-power engine has a cylinder 8½ in. in diameter by 12-in. stroke. In other features it is similar to the preceding, but develops 35 brake horse-power.

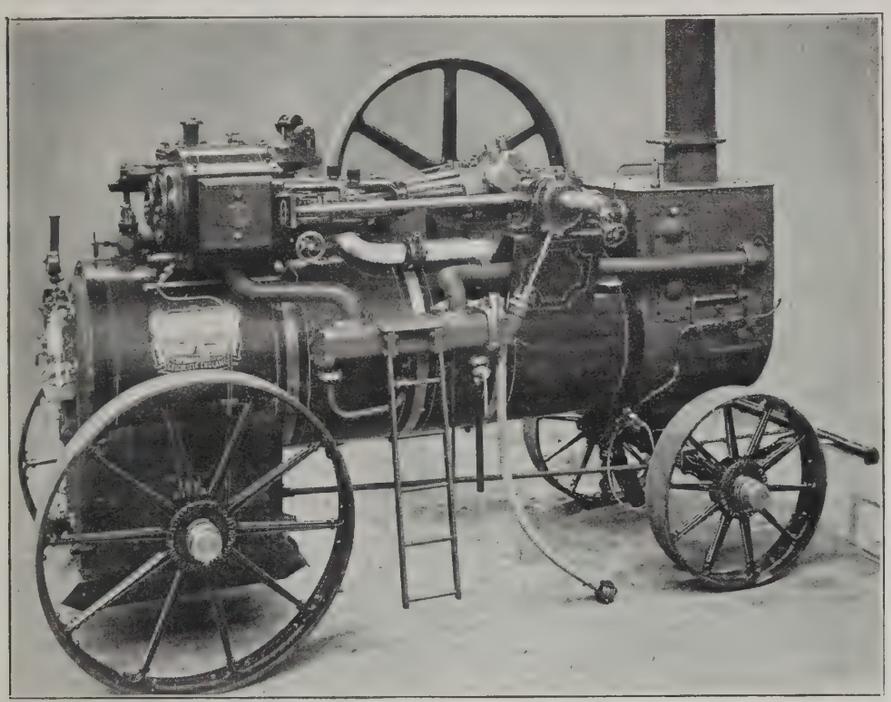

FIG. 10.

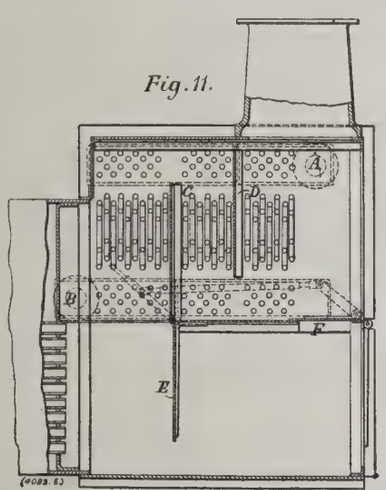

Fig. 11.

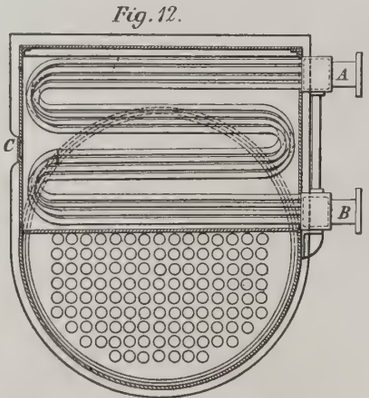

Fig. 12.

FIGS. 10 TO 12. PORTABLE ENGINE WITH SUPERHEATER; MESSRS. DAVEY, PAXMAN AND CO., LIMITED, COLCHESTER.

Messrs. J. and H. McLaren, of Leeds, exhibit various agricultural engines and tractors, but mostly to their standards. The one exception is, perhaps, an 8-horse-power compound agricultural locomotive; but this is properly a revision of a standard type, and not essentially a new design. A 5-ton steam-tractor exhibited by this firm is fitted with their superheater and feed-heater. The superheater is accommodated in the smoke-box above the level of the boiler flue-tubes; it consists of four coils of pipe, round which the waste gases circulate. The coils are placed horizontally and longitudinally, two on either side of the centre line, superposed; steam is brought from the boiler to a header, and distributed between the two pairs of coils, each stream passing through two coils and thence to a header connected with the throttle. Superheat of about 100 deg. Fahr. is obtained with this arrangement in normal working, with higher temperatures when the engine is working hard. The feed-water heater consists of a single coil of pipe in a barrel or cylinder placed horizontally across the boiler-barrel. It is on the pressure side of the pump, is fed by part of the exhaust steam from the cylinders, and heats the feed to about 200 deg. Fahr.

A steam-tractor with an interesting new feature was to be seen at the stand of Messrs. W. Tasker and Sons, Limited, Andover. This is fitted with Hoare's system of spring mounting for the rear wheels, which are chain-driven. The engine is a compound, with 5-in. and 7¾-in. cylinders and 8-in. stroke. It has three speeds and a balanced crank. On each side of the engine is a strong girder, underneath which is the spring mounted direct on the axle. The springs are long and allow of a 3-in. deflection, which is much more than is obtainable with the ordinary rear springing. The movement is taken care of by radius-rods fixed to the axle and frame. These are adjustable to allow for alteration in the chain-length. The first drive is, as usual, by spur-gears; but the second drive, as already stated, is by chain. The arrangement is one which makes the various parts very accessible.

Messrs. Aveling and Porter, Limited, of Rochester, exhibit several of their well-known types, including traction-engines, road-rollers, &c. One of their 10-ton rollers is fitted with Morrison's patent scarifier, a device which is housed in a frame attached to one side of the engine at the rear. The housing is tied by stiff bars to the back axle outside the wheel and accommodates an adjustable frame, which can be raised and lowered. This frame carries digger points, three facing in one direction and three the other, their inclination to the road surface being also adjustable by a lever and quadrant.

At the stall of Messrs. Mann's Patent Steam Cart and Wagon Company, Limited, Hunslet, there is to be seen a steam-roller primarily intended for road-patching work. This machine has a tipping body for carrying the patching material. This body is replaceable by an ordinary body or a water-tank. In addition to two other standard machines, this firm shows a steam-tractor having a horizontal compound engine mounted on a locomotive type boiler working at 200 lb. pressure. The total weight of the machine all included is 4¼ tons, and the wheels have a total width of 4 ft. 8 in., so that the weight works out at less than 1 ton per foot. The tread of the front wheels is inside that of the back, and the land is, therefore, not compressed by the machine. At the back end is a large tank, sufficient for half a day's work, the top of this tank being flat, and capable of carrying a load of 2 tons, in addition to which 6 tons may be hauled behind on a trailer. The machine will pull a four-furrow plough, working 8 in. deep, or two self-binders, and can be used to drive thrashers, &c.

At the stand of Messrs. Ruston, Proctor and Co., Limited, Lincoln, the most interesting exhibit is, perhaps, a new type of side-tipping trailer. In this vehicle, of which we intend to give illustrations next week, the body is supported by twelve small wheels, of which four are carried in bearings fixed to the chassis, while eight are attached to the tipping-body. Above the former and fixed to the underneath of the body are two ⊓-section rails, rails of a similar section but inverted being fitted on the chassis top, below the wheels attached to the body. The body is first traversed and then tipped. The traversing motion is derived from two square-threaded screws placed transversely across the chassis frame and both driven simultaneously by a hand-crank, bevels and a longitudinal shaft. On each screw is a toggle, normally flattened out, and two units, of which one is threaded and works on the screw, while the other is without a thread, and merely slides along the screwed spindle. The sliding-nut is nearest the centre of the machine to start with, with the screwed nut nearest the side from which the screw is being worked. Beyond the sliding-nut is an upright lug, which pushes the body over on the rails. As soon as the traverse is completed the sliding-nut can move no further, and the toggle closes up. This causes the body to tip. One continuous screwing

motion is all that is required of the operator, from start to the end of tipping. The body tips about a centre formed in the kink of two stirrup-irons which span the chassis, the axles of a pair of the wheels engaging in these at the end of the traverse, preventing further movement of that type and converting the traverse into tipping. To draw back the body the toggle first flattens out, the toggle-pin engaging with two Z-bars under the body, pulling the latter down. This toggle-pin, when the toggle has flattened out, comes up against stops on the Z-bars, and as the threaded nut is screwed back the body is pulled into the central position again on the chassis. The body tips to an angle of 40 deg. The tipping-gear is in duplicate, and can be worked from either side to tip on the opposite side, the only preliminary being to turn down two stops on one side or the other. At each end of the body is a rail under which the hooked ends of the side-door levers are engaged during traversing and tipping. One door runs the length of each side, and on the body being tipped the doors are opened automatically by the levers being held while the body tips. The doors are fitted with several wedges, which engage with and disengage themselves from sockets on the body. The wagon can be tipped by one man, the load falling completely clear of the wheels, emptying being completed in 1½ minutes from starting the traverse.

Messrs. Ruston Proctor's other exhibits include steam-tractors, a wood-refuse suction-gas producer and 33-brake-horse-power engine, and also several oil-engines, working with petroleum or crude oils. In the cooler applied to one of these engines, fitted up as a portable engine, the water is taken to the top of a water tower, and from there trickles down vertical fibre-ropes to the tank below the frame.

(To be continued.)

NOTES FROM THE UNITED STATES.

PHILADELPHIA, June 24.

THE only branch of the iron and steel industry normally active is the tin-plate industry, which is running at maximum capacity. It is now threatened with a strike in sixteen of the larger mills, which, if it occurs, will occasion serious inconvenience. The steel-makers are confident that better times are in sight, and there is no unusual struggle to get business. The next branch is steel plate. The week's business shows further expansion, because of the enlarging individual demand for minor requirements. During the past month Australian rail orders foot up 56,000 tons. The Queensland Railway has ordered 16,000 tons from the Maryland Steel Company, and the New South Wales Government has ordered 5000 tons from the Lorain Steel Company. So far the Pennsylvania has ordered 25,000 tons under improved specifications. The freight-rate decision is awaited daily, and much business awaits its rendering. General structural business for the week amounts to 35,145 tons, against 22,725 tons for the previous week. Improving tendencies are manifest. Platemakers figure out they can fill orders for the early summer on 60 per cent. of capacity. Orders offered at less than current rates have been rejected, notwithstanding mills could increase their output 40 per cent. Billets are inactive at 20 dols. Urgent summer requirements have been covered. The probable course of the steel market can be safely outlined by remembering capacity has not been very greatly expanded for some time, while the country's needs have been galloping ahead. The sheet mills are gaining in orders. Bar mills get barely enough business to keep going. Pipe foundries are crowded. Demand for tanks is stronger. Nails are active. Spike output is low, because of restricted railroad building. The larger foundries and engineering plants are slow and cautious buyers.

THE BATTLESHIP "ESPANA."—Sir W. G. Armstrong, Whitworth and Co., Limited, and Vickers Limited, have received a telegram from La Sociedad Espanola de Construccion Naval informing them that the new first-class battleship Espana, carrying eight 12-in. and twenty 4-in. guns, has passed through her gun trials at sea with complete success, giving the greatest satisfaction to the Spanish authorities, of whom the following were present:—Captain-General Barriere, Rear-Admiral Moreno Eliza, General Gallardo, General Gonzalez, Colonel Marabotto, and Colonel Fernandiz the ship being in charge of Captain Carranza. Rounds were fired from each gun in succession, and a final broadside with guns fully elevated. The Espana stood this severe test without the slightest deformation to structure, reflecting great credit on the builders, who are La Sociedad Espanola de Construccion Naval. The vessel was built at the Government Arsenal, Ferrol, and the guns supplied half by Sir W. G. Armstrong, Whitworth and Co., Limited, and half by Vickers Limited.

NOTES FROM CLEVELAND AND THE NORTHERN COUNTIES.

MIDDLESBROUGH, Wednesday.

The Cleveland Iron Trade.—The pig-iron market is weak and lifeless. Values show a downward tendency, and but for the very excellent statistical situation prices would doubtless be much lower than they are. As it is current rates are considerably below cost of production, and makers talk of putting furnaces out of operation. Sellers of pig-iron are prepared to make concessions to secure business, but buyers are very slow to take advantage of the lower rates named. Fears are now entertained that the dry summer on the Continent may check deliveries abroad, as the canals and rivers used to convey imports up country promise to be low and unnavigable. Political affairs continue to have a disturbing influence on the market, and, in addition to all other detrimental contributions, the present is what is usually the quietest time of the year. Under normal conditions traders look for little business between now and about the middle of August, by which time buying should commence to meet autumn and winter requirements of customers abroad. No. 3 g.m.b. Cleveland pig is on sale at 51s. 3d. f.o.b., and that is regarded as the general market quotation, though some of the leading makers ask a rather higher figure; whilst No. 1 is 52s. 9d.; No. 4 foundry, 51s.; No. 4 forge, 50s. 6d.; and mottled and white iron each 51s.—all for either early or forward delivery. Very discouraging accounts are given of the East Coast hematite branch of the staple industry. Second hands offer Nos. 1, 2, and 3 freely at 59s. for practically any delivery, and some makers will also accept that figure, but several leading producers declare that they will not sell at anything like the price named. Consumers of hematite point out that scrap steel is plentiful and cheap, and that to a considerable extent they are taking it in place of hematite pig. Foreign ore shows signs of movement. Sellers are understood to be prepared to make contracts on the basis of 17s. 3d. ex-ship Tees for Rubio of 50 per cent. quality. Durham coke maintains its value, notwithstanding Yorkshire competition. For average quality of Durham blast-furnace coke delivered at Tees-side works, 17s. 6d. is generally named.

Stocks and Shipments.—The stock of Cleveland pig-iron in the public warrant stores now stands at 78,289 tons—all of which is No. 3 quality. During the month of June stocks of Cleveland pig-iron were reduced by 4947 tons. Shipments of pig-iron from the Tees during the month of June were on a moderate scale, averaging 3476 tons per working day, the total despatches being returned at 86,907 tons, 76,207 tons of which went from Middlesbrough and 10,700 tons from Skinningrove. In May the loadings reached 94,174 tons, or a daily average of 3767 tons; and for June, a year ago, the clearances were given at 95,403 tons, or an average of 3677 tons per working day. Of the iron shipped from Skinningrove, 10,224 tons went to Scotland and 476 tons to Holland. Of the iron cleared at Middlesbrough, 53,955 tons went foreign and 22,252 tons coastwise. Scotland was again the largest buyer, receiving 13,914 tons, whilst Sweden imported 7089 tons; Italy, 6721 tons; France, 6617 tons; Germany, 4928 tons; Japan, 4615 tons; and Holland, 4403 tons. Of the 8227 tons of manufactured iron loaded on the Tees 3912 tons went abroad, and 4315 tons coastwise, and of the 46,796 tons of steel shipped, 41,334 tons went foreign and 4962 tons to home customers. The Argentine took 2011 tons and India 1167 tons of manufactured iron, whilst India was the largest buyer of steel, with an import of 14,206 tons. Other principal buyers of steel were:—West Australia, 8330 tons; the Argentine, 4200 tons; New South Wales, 3082 tons; New Zealand, 2574 tons; Victoria, 1955 tons; and Russia, 1925 tons.

Manufactured Iron and Steel.—There is little new to report concerning the various branches of the manufactured iron and steel trades. Business is quiet, and specifications for shipbuilding material are coming in very slowly. Constructional steel, however, is showing more activity, and new orders are coming forward more freely. Principal market quotations stand:—Common iron bars, 7*l.*; best bars, 7*l.* 7s. 6d.; best best bars, 7*l.* 15s.; packing iron, 5*l.* 5s.; iron ship-plates, 6*l.* 15s.; iron ship-angles, 7*l.*; iron ship-rivets, 7*l.* 5s.; iron girder plates, 7*l.* 5s.; steel bars (basic), 6*l.* 5s.; steel bars (Siemen's), 6*l.* 5s.; steel ship-plates, 6*l.*; steel ship-angles, 5*l.* 15s.; steel boiler-plates, 7*l.*; steel joists, 6*l.* 12s. 6d.; steel strip, 6*l.* 5s.; steel hoops, 6*l.* 10s.—all less the customary 2½ per cent. discount; cast-iron columns, 7*l.* 7s. 6d.; cast-iron railway chairs, 4*l.* 5s.; light iron rails, 7*l.*; heavy steel rails, 6*l.*; steel railway sleepers, 7*l.* 5s.—all net at works; galvanised corrugated sheets, 24 gauge, in bundles, 11*l.* 5s. f.o.b.—less 4 per cent.

UPPER CONGO RAILWAY.—The expenditure on capital account made by the Upper Congo Railway Company to the close of last year was 3,171,254*l.*, showing an increase of 514,653*l.*, as compared with the corresponding outlay made to the close of 1912. The rails upon the third section of the company's railways, which will unite the Lualaba to Lake Tanganyika, had reached a length of 138¾ miles at the close of May, leaving a gap of 30⅝ miles still to be made good. The works which have been proceeded with of late have not advanced so rapidly as had been hoped and expected. Regular progress has, however, been made upon the whole. Two steamers, with a displacement of 750 tons each, have been ordered for service on Lake Tanganyika. Each of these steamers will be fitted with engines working up to 400 horse-power, and a speed of 8½ knots per hour is to be maintained. The steamers are 173 ft. long by 28 ft. beam.

NOTES FROM THE SOUTH-WEST.

Cardiff.—The steam-coal trade has continued quiet, owing to the uncertainties attending the strike of marine engineers. Tonnage arrivals over the week-end were rather heavier, notwithstanding the strike influence, and loading operations appear to have proceeded without interruption. At the same time, several large collieries are idle in consequence of excessive stocks. The prevailing opinion among sellers is that the market is more likely to stiffen than to relax. The best Admiralty large steam coal has made 20s. to 21s.; best secondary qualities have brought 18s. 6d. to 19s. 6d.; other secondary descriptions, 17s. 6d. to 18s.; best bunker smalls, 10s. 9d. to 11s.; and cargo smalls, 8s. 6d. to 8s. 9d. per ton. The best household coal has been quoted at 19s. to 20s.; good households have made 17s. to 18s.; No. 3 Rhondda large has brought 17s. 6d. to 17s. 9d.; and smalls have made 12s. to 12s. 6d. per ton. No. 2 Rhondda large has realised 12s. 6d. to 13s., and No. 2 smalls have made 8s. 9d. to 9s. 6d. per ton. Special foundry coke has been quoted at 25s. to 27s.; good foundry coke at 20s. to 23s.; and furnace coke at 17s. to 19s. per ton. As regards iron ore, Rubio has made 16s. to 17s. per ton upon a basis of 50 per cent. of iron and charges, including freight, insurance, &c., to Cardiff or Newport.

Bristol Wagon Company.—The directors of the Bristol Wagon and Carriage Works Company, Limited, report that the balance available for distribution is 12,379*l.* The directors recommend a dividend upon the ordinary share capital for the past half-year at the rate of 5 per cent. per annum, carrying forward 6879*l.*

Tredegar.—Lord Aberconway presided at the forty-first annual meeting of the Tredegar Iron and Coal Company, Limited, held in London, on Friday. In moving the adoption of the annual report, the chairman said the price of coal, except in the case of small coal, was well maintained during the past year. The shipping engineers' strike was a serious factor in South Wales. It had quite disorganised trade, and if it continued, it was highly probable that there would be considerable stoppages of collieries. Sir Arthur Markham seconded the adoption of the report. This was carried, and a dividend of 10 per cent., with 2½ per cent. bonus, was declared.

Finances of Cardiff.—The gross income from the sale of electricity for lighting and other purposes showed a further increase as compared with 1912-13, the gross total being 58,751*l.* From the sale of current there has been a continually increasing income, the figures for the past four years being:—1910-11, 34,959*l.*; 1911-12, 37,800*l.*; 1912-13, 42,574*l.*; 1913-14, 47,503*l.* The capital expenditure on new services, cables, &c., during the past year amounted to 7244*l.* From water and meter rentals there was an income, after deducting voids, irrecoverables, &c., of 76,453*l.*, as against 73,244*l.* in 1912-13, and 71,940*l.* in 1911-12. The water works were rate-aided during the year to the extent of 10,033*l.*, and the total amount levied in that way since 1890 has been 210,764*l.* A rate-in-aid is unavoidable at present. The capital expenditure during the year on water works was 72,784*l.*, most of it being in connection with a new reservoir.

Dowlais.—The Dowlais works have been actively employed, the Bessemer and Siemens furnaces going at high pressure. The Goat Mill has turned out a large quantity of heavy rails, sleepers, billets, &c., and these have been sent away to several South Wales ports for shipment. The Big Mill has produced underground arches and tram-rails; a heavy tonnage of fish-plates has also been despatched.

Closing-Down Collieries.—As a result of the recent amalgamation of the London City and Midland Bank with the Metropolitan Bank of England and Wales, the London City and Midland immediately took up a decided position with regard to the Bedminster, Easton, Kingswood, and Parkfield Collieries. After the men had been paid a week's wages the collieries were closed-down.

Bristol Docks.—In the seven weeks ending with June 20 there was a traffic increase of 8068 tons foreign, a traffic decrease of 650 tons coastwise, and an increase of 215*l.* in dues, as compared with the corresponding period of 1913.

THE RUSSIAN NAVY.—The Budget Commission of the Russian Duma has voted a credit of 12,000,000*l.* for the construction of three ironclads with a displacement of 27,000 tons each, two cruisers of 7500 tons, eight torpedo-boat destroyers, and six submarines destined for the Black Sea. These vessels are to be built at Nicolaieff, under the direction of the Vickers connection, and they are to be completed at the latest by the spring of 1917.

SUBSIDISED LORRY TRIALS.—In our issue of May 22 we dealt at length with the War Office scheme for subsidising motor-lorries for use in time of war, and with the trials which were then being held. A report of the trials has now been issued. At the request of the manufacturers whose vehicles were being tested, no figures are given which can be taken as showing competitive results. It is stated that, generally speaking, the performance was satisfactory, and that there were very few road stops or breakdowns. The consumption averaged 54 gross ton-miles per gallon of petrol for the whole of the trial. At the conclusion of the trial the committee decided to grant certificates to the following firms:—Messrs. Commercial Cars, Limited, class "A" lorry; Messrs. Dennis Brothers, class "A" lorry; subject to tests of improved type of engine being carried out to the satisfaction of the War Department, Messrs. Leyland Motors, Limited, class "A" lorry. The question of granting a certificate to another firm is still under consideration.

NORTH-EASTERN MARINE ENGINEERING CO.'S WORKS, WALLSEND.

When one remembers the large preponderance of cargo-carrying ships in the world's fleet and the immense importance to industry and general economy of living of low freight rates and the highest propulsive efficiency of the general trading ship, it is appropriate that the naval architects during their forthcoming meeting at Newcastle-on-Tyne should visit several of the works producing the machinery of such vessels. As typical of such factories, we illustrate the Wallsend establishment of the North-Eastern Marine Engineering Company, which is to be visited on Wednesday, since these works, under the management of Mr. Summers Hunter, have not only a very large output, but aim, both in experimental work and design, to assist towards the higher efficiency of the propelling machinery of general carrying ships. The company had its origin in 1865, beginning with their establishment at Sunderland, where 1200 men are now employed, and the Northumberland Works at Wallsend were commenced in 1882, and here the number of workmen is 2000. Both establishments carry out the same operations, and are assisted by the company's Northumberland forge, which is situated at Wallsend-on-Tyne, and produces per annum about 2500 tons of forgings of all classes. The general equipment of the two engineering works is somewhat similar, except that at Wallsend the works are on a larger scale, and capable of dealing with larger engines and larger vessels; at the same time the facilities at the two works enable the principal management, which is concentrated at Wallsend, to apportion the work between the two establishments, with a view to the best delivery and the most economical results. As to the capacity of the works, the largest output of the combined concern was in 1912, when the collective power of the marine engines built was 129,125 horse-power, but the average is about 95,000 horse-power, and this is fairly evenly distributed in proportion to their capacity between the two factories. The power of the machinery, as a rule, ranges up to about 6000 horse-power. The naval architects, when they visit the works, will find a fairly representative volume of work in course of execution, there being now in progress engines ranging between 2000 and 6000 indicated horse-power.

As regards the design of machinery, every effort is made to work to standards, varying only in the power to be developed, and it is satisfactory to note that in the great majority of instances the economy attainable by these means appeals to the engineering officers of clients; however, when dealing with vessels for special trades, modifications have to be made to suit varying conditions or ideas. Generally speaking, standard patterns for the merchant engine are used time and again, particularly for main castings, such as bed-plates, cylinders, columns, and slide-valves. Nothing very definite can be said as to the preference for triple or quadruple-expansion engines, but many well-known ship-owning firms are now adopting the latter, which have proved very economical, more especially on long-distance voyages. For standard engines the company have adopted 180 lb. pressure per sq. in. for triple-expansion engines, and 220 lb. per sq. in. for quadruple engines. On inquiry at the works in reference to the use of cast-iron or wrought-iron circular columns in the front of the engine, we were told that most owners preferred wrought-iron, but in other cases the view taken was that cast-iron box columns of the A-frame type, although they did not give the same degree of accessibility to the working parts, made a stiffer job, but were heavier.

Again, as to crank-shafts, some years ago the introduction of hydraulic forged ingot steel led to the built-up type of crank-shaft, and this is now the general practice in the merchant engine, the advantages of this type being well understood. In the machine-shop a Bunsen-burner furnace is fitted for the shrinking on of the crank-pins and end pieces. Another important feature of the North-Eastern Company's work is the extent to which superheating is applied. They were first in England to take out a license for the Schmidt superheater, and during the last three years have installed them in nineteen vessels, having a collective power of 42,000 indicated horse-power. At the present time they have orders in hand to instal the system in thirty more vessels. The combination of such superheaters with the latest design of quadruple-expansion engines results in very high economy in steam consumption, and the firm are developing the system in connection with Parsons marine geared turbines, so that still better results will be realised. In this connection it may be said that the firm have in use an experimental boiler of 700 horse-power, with which a continuous series of experiments is carried out on this and similar problems. Another point illustrative of the progressive character of the company's work has reference to the practice regarding the Diesel engine. Having considered the question of adopting the oil-engine for the propulsion of general carrying ships, they entered into an agreement a few years ago with the Nederlandsche Fabriek Werkspoor, of Amsterdam, for the building of the type of engine constructed by this celebrated Dutch firm. Since then they have done a considerable amount of work for the Netherlands firm, although they have not completed an entire set of Diesel engines. Their work has mostly been in the direction of making castings in their iron foundry, but when increased demand for this type of propelling engine justifies it, the firm intend to build entirely new shops for the production of the Werkspoor type of engine. This, it may be said, is of the four-stroke-cycle direct-acting type, with crosshead guides and open front and drip-feed lubricators, the company being inclined to the view that the four-stroke-cycle type of engine can be constructed for power sufficiently

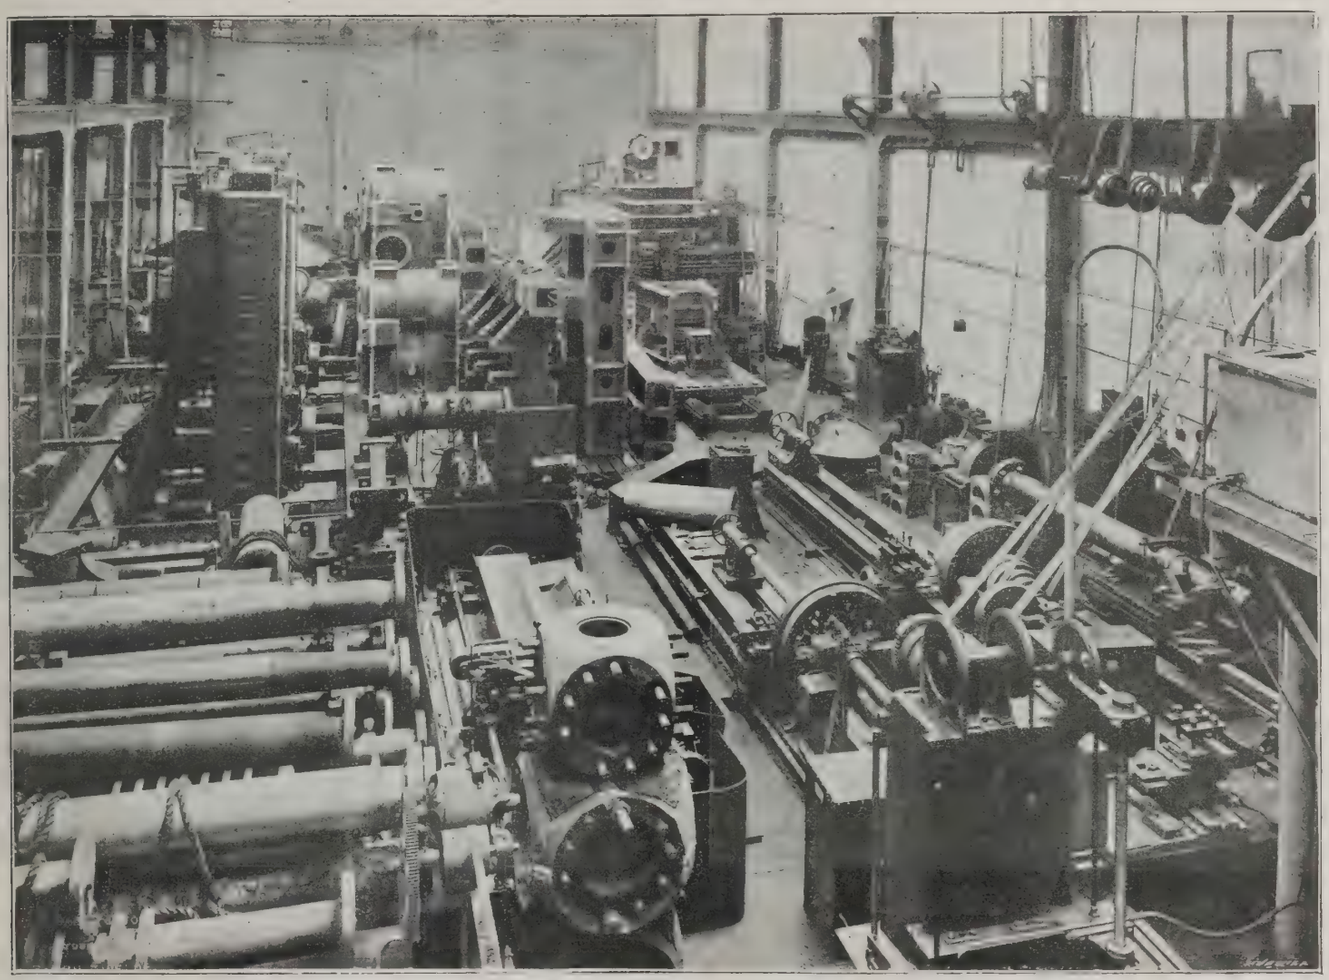

Fig. 5. Shafting-Shop.

high for the class of ship with which they deal, and that it is therefore desirable to ensure the measure of simplicity and reliability that the four-stroke-cycle engine gives.

A direct consequence of the work done in making castings for the Werkspoor Diesel engine has been the establishment and equipment of a metallurgical laboratory. At the same time a considerable amount of research work is being done in connection with the castings for ordinary steam work.

The laboratory, which was started about three years ago, employs a staff of six chemists, and is equipped with the most modern apparatus. The most noticeable are a 50-ton Buckton tensile-machine, a Krupp bending-test machine, a metallographic outfit, and a very recent type of Foster double-purpose radiation pyrometer. Here, too, are collated the records of every casting in the iron foundry, embracing a whole system of foundry control, from the pig-irons entering the cupolas to the castings leaving the machine-shops. It is the floor of the shops terraced in three great steps. Thus the upper ends of the bays of the main building are utilised for the small machine-shop, brass-foundry, brass-finishing shop, smithy, tool-making and fettling department, &c., the roof being 47 ft. from the ground-level. On the second terrace there are the larger machine-shops and the erecting-shops, the height here being 54 ft , while nearer the river again there is, at a level 5 ft. to 8 ft. lower, a shafting-shop, boiler machine and erecting-shops, &c. The foundry occupies two more of the bays at the lower levels. In all cases, however, the overhead cranes in the bays travel the whole length of the shops, and therefore command also the smaller machine-shops. These cranes, in the most important bays—namely, the engine-erecting shop—are respectively of 100, 60, 20, and 10 tons capacity. In the boiler machine-shop there is a 60-ton, a 40-ton, a 25-ton, and two 10-ton cranes. In the fitting-out portion of the boiler-shop the cranes are so arranged that weights up to 150 tons can be conveniently dealt with, the heaviest boiler built so far being over 120 tons. The machinery is dealt with alongside the ships by a 150-ton cantilever crane, built by Messrs. Sir William Arrol and Co., Limited, Glasgow ; the lifting gear by Messrs. Stothert and Pitt, Limited, Bath. The practice at the works is to transfer from the erecting-shop to the ship complete triple-expansion engines up to 2000 horse-power, including the cylinders, columns and bed-plates, the condenser and the pumps worked from the cross-heads being alone separated. In the case of larger engines, the bed-plate, the crank-shaft, connecting-rods, eccentric rods, links and columns are lowered into position first. All the cylinders, even in the case of quadruple-expansion engines, are placed on their columns in one lift.

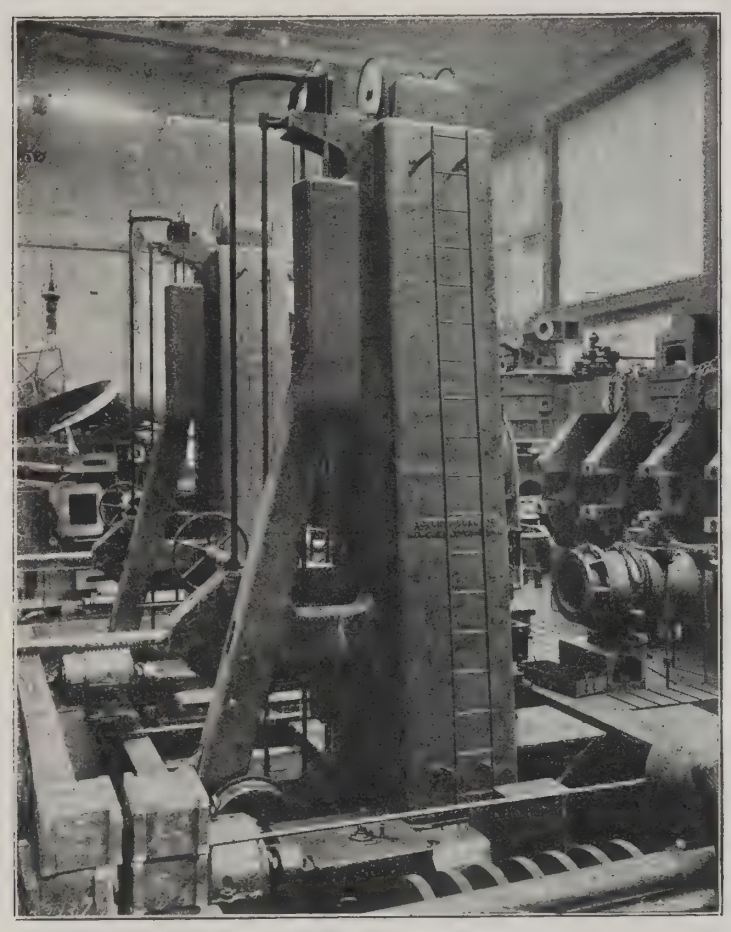

FIG. 6. CYLINDER-BORING MACHINE.

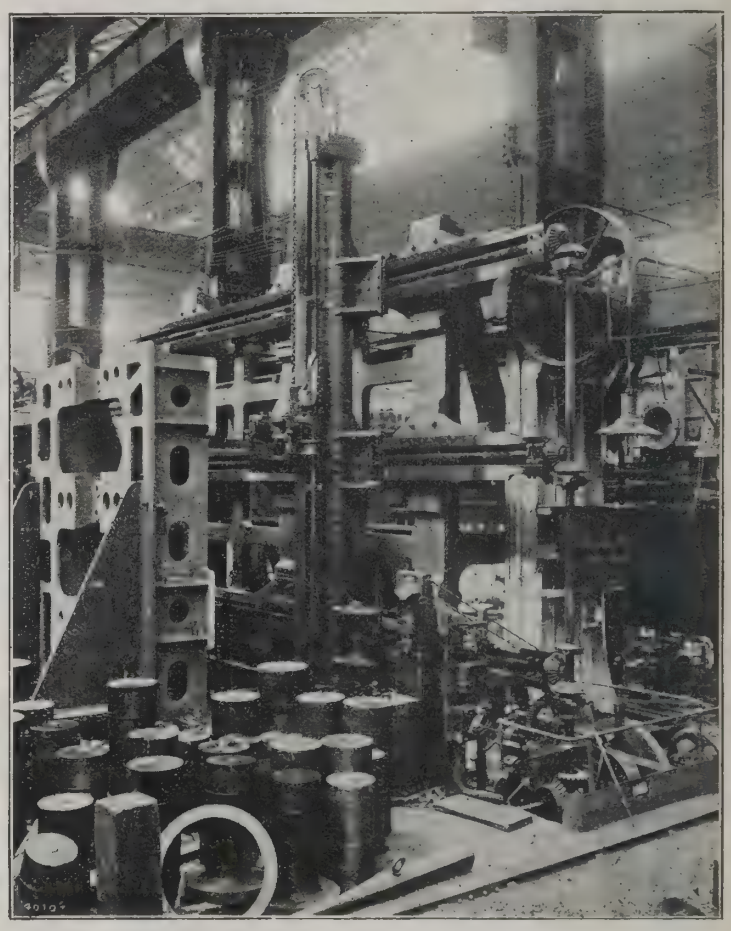

FIG. 7. HORIZONTAL AND VERTICAL PLANING-MACHINE.

In dealing with the manufacturing shops, we may begin with the pattern-shop, which is a separate building in close proximity to the iron foundry, and is fitted with the usual wood-working machinery, including circular saws, band-saws, planing and spindle machines, sand-papering machines and lathes. The iron foundry, Fig. 1, Plate VIII., occupies two of the bays of the main shops, to which reference has already been made. The largest casting within recent times was a bed-plate weighing 45 tons. The influence of the laboratory on the iron foundry is most marked. Previously it was thought that rule-of-thumb methods were sufficient, but gradually it became evident that cast iron was as sensitive to treatment as any other complicated alloy, as, for instance, propeller bronze. Since many vital parts of a marine engine consist of cast iron, it became clear to the company that the efficiency of the engine was largely dependent upon a metal which not only was not understood, but which was not even under control. This is now all changed ; the pig-irons are analysed upon arrival, and each mixture is altered accordingly. By continual study of this and of cupola conditions, it is now found possible to produce castings of any required composition. Thus has this company solved a problem which too long has remained a difficulty with many British firms, and which Continental makers have tackled to their own advantage. As already mentioned, an inspection of the records shows a marked improvement in the quality of the metal. Moreover, the fact that the metal of every casting is now like that of every other casting of its class should, in itself, be logical proof of the incalculable value of the system to users of marine engines.

There are three cupolas, built in an annexe to the foundry, the melting capacity being respectively 8, 6 and 4 tons per hour. Baker blowers are used. The charging platform is at the top of the furnace, the material being raised by cranes. There are seventeen casting-pits, the largest being 23 ft. by 13 ft. 6 in. and 16 ft. by 19 ft. These are used principally for making bed-plates. There are six core-drying stoves with a total area of 16 ft. by 30 ft.

The large machine-shop, Fig. 2, Plate VIII., is 350 ft. long and of 60 ft. span, with a 40-ton crane, having an auxiliary lift of 10 tons, and a 10-ton crane. The principal machines in the department are a boring-mill, Fig. 6, above, to take cylinders up to 108 in. in diameter, table planers taking jobs 16 ft. by 8 ft. by 8 ft., and a 10-ft. chuck-lathe for boring small cylinders. A new lathe with 66-in. centres is in course of installation. There is a large horizontal and vertical planer, Fig. 7, above, to deal with surfaces 20 ft. horizontally and 17 ft. vertically, also shafting-lathes with 30-in. centres and 36-ft. bed. The marking-off table is placed at the end contiguous to the foundry, so that

claimed that all castings of the same class are produced alike in analytical composition and in physical qualities, and that thus their reliability and constancy are greatly enhanced. Since the introduction of this system, the quality of the metal has much improved, as is shown not only in the complete records kept by the departments, but also by the experience of those who have to work the metal in the various workshops. The testing of fuel and lubricating oils, gun-metal, and bearing metal, forms another important branch of the work. There is an experimental casting-room, and research work is constantly in progress. It may be mentioned that for some time past, Dr. J. E. Stead has been working in collaboration with the chief chemist at the works, and has helped him to make the department of real practical value to the works, as well as a place of investigation into the many problems constantly arising in the practice of modern marine engineering.

As regards the manufacturing shops, an admirable adaptation has been made of the conformation of the ground on which they were erected. There is a fairly steep slope to the river here as elsewhere along Tyneside, and the main buildings are constructed on this slope, stretching from the railway sidings and offices down to near the river jetty. The roof of the buildings has been made level, and

the castings, after being cleaned, pass direct to the tables and thence to the machines, and thus traverse the minimum distance. Many of the machines are driven by separate motors and others by belting from overhead shafts, which are operated by electric motors.

The small machine-shop occupies the upper part of one of the bays, and can be entered from the erecting-shop or from the blacksmith's shop which adjoins. It is fitted with the usual lathes and planing, milling, drilling, and slotting-machines. Around it, again, there is a gallery equipped with special grinding, high-speed drilling and other machines, and here all the smaller details of the engines are fitted together and lowered straight to the erecting-shop. Some of the later machines will be examined with interest, notably new high-speed drilling-machines by Messrs. A. A. Jones, Pollard and Shipman, a "New Century" drill by the same makers, and gap-lathes by Messrs. Pollock and MacNab. The blacksmith's shop, which supplies many of the smaller forgings to be machined in these two departments, has fifteen fires, with forging-hammers which are worked with air superheated by the waste heat from the blacksmiths' fires. There are also in this department bolt and rivet-making plants. It will be understood, of course, that the heavier forgings come from the company's Northumberland Forge, to which reference has already been made. The brass-foundry and finishing-shop is also contiguous to this small machine-shop, and here all the fitting and machining of valves, cocks, superheaters, and other small work is undertaken, there being a satisfactory installation of lathes and drilling-machines. Two new lathes of the "all-gear" type have been fitted recently, and enable a large range of speeds to be obtained; as many as fifteen different speeds are possible. Another tool which will interest visitors is a new Lang turret lathe for bar work. The tool-making and fettling-shop, as already mentioned, is also in this part of the main building, and its equipment includes annealing and tool-hardening furnaces. Special note may be made of the tool-grinding machinery.

The location of these various shops greatly simplifies the convergence of the various units, when completed, towards the engine-erecting shop. This shop, Fig. 3, Plate IX., is laid with a concrete base for the building-up of the engines, and the cranes in use, as we have said, range up to 100 tons. Close by it is the shafting-shop, Fig. 5, page 25. In this shop are several very heavy lathes, but perhaps more notable still is a large horizontal drilling-machine with two 6-in. spindles, and a large planer fitted with Lancashire drive, to work surfaces 8 ft. 6 in. by 8 ft. 6 in. by 18 ft. These machines plane and drill bed-plates, cylinders, columns, &c.

A new coppersmith's shop has recently been built near to the jetty at which the vessels are fitted out. This department is 65 ft. by 60 ft., and its equipment includes pipe-screwing, cutting, and hydraulic bending-machines capable of dealing with copper and steel pipes of the largest size. There are the usual fires, blasts, &c.

The boiler-shop, Fig. 4, Plate IX., is in three of the bays in the main building, and each is 450 ft. long, the large fitting-out bay being at the end of the engine-erecting shop, where cranes capable of dealing with lifts up to 150 tons are available. As to practice in connection with the design of boilers, the management state that the double-ended boiler has advantage in respect that it is cheaper to build, lighter in weight, and takes up less space than single-ended boilers for the same power; there is a distinct tendency in its favour for general carrying ships. At the present time there are being constructed boilers each equal to 2500 horse-power. The largest double-ended boiler constructed at the works has a diameter of 17 ft. 1½ in., and a length of 21 ft., the heating surface being 6450 sq. ft. It was built to work under Howden's forced draught, which is very extensively in use in the merchant service, and the total weight, with fittings, is about 121 tons. The largest single-ended boilers were of 17 ft. diameter and 11 ft. 6 in. length, weighing 64 tons, and 16 ft. 3 in. in diameter and 12 ft. long, weighing 70 tons. A feature of the North-Eastern Company's boiler is the system of combustion-chamber wrapper-plate. The plate is rolled in one piece, and the joint is made near the top; there is thus only one joint, instead of two, as in other combustion-chambers, and the joint, being placed high up, is not exposed so much to the action of the flames.

The shell-plates are rolled by a set of rolls capable of dealing with plates up to 13 ft. 6 in. wide and 2 in. in thickness. The largest flanging-machine has a ram capable of exerting a pressure of 110 tons, and a smaller machine of 80 tons. The riveting and shell-plating is done either on a 13-ft. 6-in. or 11-ft. 6-in. gap-riveter, while a smaller tool is used for combustion-chambers, and in addition a number of portable hydraulic riveters are available. There is an interesting tube-hole cutting-machine and a boiler-back drilling-machine. There is also a set of bending rolls for bending angle-irons into rings. There are of course, the usual punching, shearing, and other boiler-making tools.

For some time back the company has been giving special attention to pneumatic appliances, their installation consisting of electrically-driven air-compressors of 600 cub. ft. capacity, working up to a pressure of 100 lb. per sq. in. Experiments have been conducted with a view to improving the pneumatic hand-tools for special operations, particular attention being given to simplicity of construction and reliability in working. In our columns we have frequently referred to the increasing use of pneumatic hammers for riveting, caulking, chipping, &c., and it is interesting to see this being taken up so actively in a modern engineering establishment. The hydraulic power for the tools in the department is maintained by two large hydraulic pumps (duplicate sets). Close to the jetty is a light iron-work shop for uptakes, funnels, &c.

The electricity for lighting and for driving the various shops is taken from the mains of the Newcastle-on-Tyne Electric Supply Company. It is used at a pressure of 250 volts on the three-wire system. Electric arc-lamps are used for illuminating the shops.

The river frontage extends over 1250 ft., and along it is a timber jetty, so that two vessels may lie in the same fore and aft line. There is a travelling-crane of 20 tons capacity, with a radius of 42 ft., traversing the whole length of the jetty. The heavier loads are taken by a 150-ton electric cantilever crane. The leading dimensions of this crane may here be tabulated as follow :—

	Ft.	In.
Height from jetty to rail-level	153	6
Height from jetty to top of tower	124	0
Total length of cantilever	238	0
Length of long arm	148	0
Length of short arm	90	0
Reach of main hook above jetty	143	0
Reach of main hook below jetty	30	0
Total range of main hook	173	0
Reach of auxiliary hook above jetty	143	0
Reach of auxiliary hook below jetty	30	0
Total range of auxiliary hook	173	0
Depth of main girders at centre	25	10
Centres of main girders	14	0
Centres of main columns	40 ft. at bottom; 35 ft. at top	
Tensile stress in members	6½ tons maximum	
Factor of safety in struts	5 minimum	
Test load, main and auxiliary	25 per cent. over full load	
Nature of foundations	4 steel cylinders	
Depth of ,,	Two 73 ft. deep and two 58 ft. deep	
To lift 150 tons at radius of	85 ft.	
,, 120 ,, ,,	100 ,,	
,, 80 ,, ,,	133 ,,	
,, 30 ,, ,, (auxiliary)	137 ,,	
Edge of jetty to 150-ton load	53 ,,	
To lift 150 tons at speed of	5 ft. per min.	
,, 100 ,,	7 ft. 6 in. per min.	
,, 80 ,,	9 ft. per min.	
,, 30 ,, (auxiliary)	12 ft. 6 in. per min.	
,, 7½ ,,	50 ft. per min.	
To traverse 150 tons at	40 ,,	
,, 30 tons at	100 ,,	
To revolve 150 tons at	1 rev. in 10 min.	
,, 30 tons at	1 ,, 5 ,,	
Distance, centre of crane to edge of jetty	32 ft.	
Weight of machinery	82 tons	
Weight of steel work	657 ,,	
Ballast	85 ,,	
Total weight of crane, exclusive of foundations	824 ,,	

This crane, it will be seen, can easily lift loads into two ships lying side by side along the berth, so that there can be great expedition in the fitting of the machinery on board.

The management have recognised the great importance of adequate commercial and office staffs, and the suite of offices is notably spacious and well arranged for an establishment of this size. It may be added further that the management have adopted a liberal policy in respect to their workmen. The piece-work system is largely in operation, and every endeavour is made to ensure suitable habitations for the men adjoining the works. We were much interested in the company's schemes for the better education and training of apprentices, and we notice they give every encouragement to youths attending the evening technical classes.

THE NATIONAL PHYSICAL LABORATORY IN 1913-14.

(*Continued from page* 882, *vol. xcvii.*)

Vibrations of St. Paul's and the Clock Tower (Messrs. Stanton and Batson).—Early in 1913 experiments on the vibrations caused by traffic on St. Paul's Cathedral were made by request of the Home Secretary with the aid of two seismographs. The one for measuring the horizontal component was of the boom type, a boom being pivoted at the inner end, and being held by a wire stretched obliquely from the top of the standard of the instrument to a point near the outer end, which was weighted. The late John Milne used such booms, but his were as light as possible, and not loaded. The instrument used for measuring the vertical component consisted of a steel bar suspended near the one end by a strong spiral spring, and weighted at the other by a weight of 6 lb.; very heavy instruments of this type are used by Wiechert at Göttingen. Kinematograph records were taken with both the instruments. Observations were made in the crypt of St. Paul's, when the traffic was normal and when it was stopped at night near the cathedral. The traffic marked itself by short undulations superposed on the long-period oscillations of the instruments; three motor-omnibuses passing made little impression when running at 6 miles per hour, but at double that speed the oscillations were distinct; yet they were only of the order of about 0.0001 in. Similar results were obtained in the library and in the whispering-gallery, and also in other experiments made in the Clock Tower at Westminster, where the instruments were mounted on the stone floor, 70 ft. above the street level; in the latter case the horizontal movements were more marked.

Dr. Stanton showed, on the inspection day, an interesting experiment due to Reynolds. When two jets of water meet one another in the same vertical plane, the one jet coming from above, the other from below, a circular disc of water is formed, from the edge of which drops are thrown off. When the lower jet is more powerful than the other the disc is slightly cup-shaped. When the two jets are not exactly aligned, the circular disc assumes a lens shape in a more or less inclined plane, not at right angles to the jets as before. Mr. Relf showed the beautiful eddies formed when a vertical cylinder of brass is placed in a slowly-flowing current of water; we have described these experiments when they were in charge of Mr. Eden, who has left the Laboratory.

Tests of Brake Linings (Mr. C. Jakeman, Mr. A. W. Judge).—An extensive research has been carried out for one of the makers of brake linings on some thirty different substances to determine the coefficients of friction under different loads, speeds and temperatures; the materials tried comprised nearly all the cotton fibre and woven asbestos linings in use; further, wood, leather and vulcanised fibre, and some experimental materials. All these substances being bad conductors of heat, block-temperature measurements were out of question, and a very fine hole was drilled in the side of the rim of the friction-wheel, very near the rubbing surface and reaching well under the part of the rim with which the friction-block was in contact. A thermo-couple of iron-eureka wire was placed in this hole, and the leads were taken along the side of the wheel and through the hollow shaft to two insulated copper discs on the shaft running in mercury troughs, from which the other connections were made. A second hole was drilled close to the former to check the measurements, and at the end of a test a thermo-couple was inserted in this hole, the copper discs being cut out; the two series of observations were in very good agreement, but the temperature measurements, made to 0.5 deg. Cent., were possibly a little too low.

The machine illustrated in Figs. 1 to 7, overleaf, comprised a cast-iron wheel A, 20 in. in diameter, 3 in. wide, mounted in bearings and having a

cast-iron friction-block holder B to hold two strips, $2\frac{1}{2}$ in. long and $\frac{3}{8}$ in. wide, of the material under test, pressed on by the lever C and the load W, while the friction-lever F and the load *w* served to determine the tangential pull due to the friction of the blocks. Fig. 1 is an end view of the machine; Fig. 2 is an elevation with one lever support removed; Fig. 3 is a plan; Figs. 4 and 5, elevation and section through shaft and friction-wheels, show details of the two holes M and M_1 and of the copper discs N_1 and N_2, the mercury trough O, and the thermo-couple; Figs. 6 and 7 explain the coupling of the friction-blocks with the links D and the screws E more fully, Fig. 6 being an end view with the end plate removed, and Fig. 7 a section through X X of Fig. 6; G is a dash-pot, J the belt, K the driving-pulley, and S the tachometer.

The wheel was driven by a belt from a 50-horse-power shunt motor, armature current being supplied at 480 or 110 volts, and further speed variation was obtained with the aid of different belt-pulleys Tests were made at rubbing speeds of 600 ft., 2900 ft., and 5900 ft. per minute, and pressures from 5 lb. to 180 lb. per sq. in. were applied to the dry materials, while with lubricated materials the pressure was raised to 290 lb. per inch maximum. The lubrication was effected by two small pipes dropping oil in front of the blocks (not indicated in the diagrams). The materials tested behaved very differently. Some broke away at the edges, some were destroyed by the heat developed; speed as such, did not appear to impose any limits, but the impregnating substance set a limit to pressure and temperature in many cases. This substance was sometimes driven out at low pressures as the temperature rose. The results are summarised for the five chief materials (tried in diverse products):—

Material.	Variation with Increase of		
	Speed.	Pressure.	Temperature.
Cotton-fibre	Nil	Increase	Increase
Woven asbestos ..	,,	Nil	,,
Wood (teak)	,,	,,	Nil
Leather	,,	Decrease	Great decrease
Vulcanised fibre ..	,,	—	Increase (but burns soon)

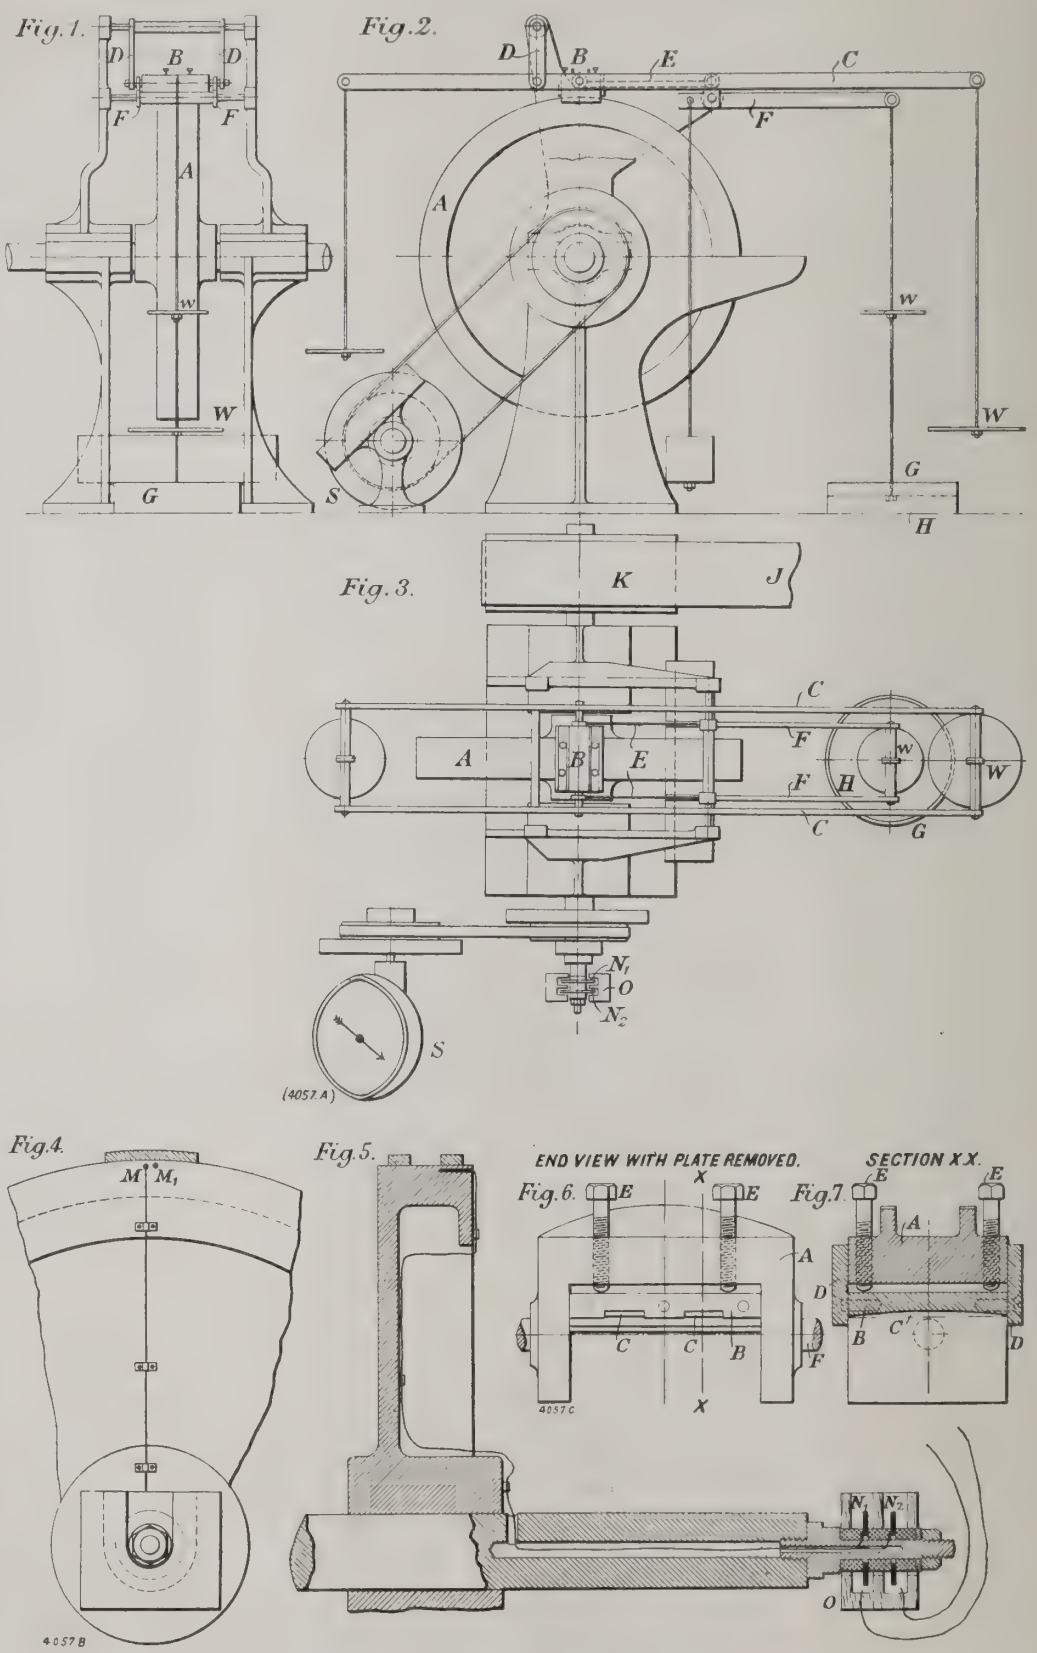
The values of the friction coefficients may be taken as:—cotton fibre, 0.55 to 0.65; asbestos, 0.30 to 0.35; wood, 0.25; leather, 0.2 to 0.8; vulcanised fibre, 0.5.

Thus cotton fibre and woven asbestos gave by far the most uniform and best results; wood rapidly charred and broke away; leather blocks would give almost any coefficient, and were rapidly destroyed a little above 100 deg. Cent.; vulcanised fibre gave a high coefficient, but was useless as brake material, because heat rapidly destroyed it. The low coefficient of asbestos (compared with that of cotton fibre) was at first ascribed to the asbestos being woven with brass wire; but some impregnated asbestos, free from wire, gave similar results, and the impregnation, which serves as lubricant, seems to be the decisive feature, because in asbestos the impregnating substance remains between the fibres (without entering them as in cotton). Lubrication reduced the friction both at high and low temperatures; but the pressure could be raised to such an extent that the same amount of energy was absorbed per unit area as without lubrication without increasing the wear. Starting from rest, the friction coefficient was found to be from 60 to 120 per cent. of the friction when running; a large increase in the friction, as in the case of metal surfaces in contact, was not observed in any case. The growing use of cotton-fibre and woven-asbestos brake-blocks seems hence to be quite justified; it was noteworthy that they answered best when polished by some wear, new surfaces giving lower friction coefficients than worn surfaces.

The Froude National Tank (Messrs. G. S. Baker, late R.C.N.C., M. Inst. N.A., G. A. Millar, B.A., J. L. Kent).—The vacancies on the Advisory Committee caused by the death of the chairman, Sir William White, and of Dr. Thearle, have been filled by electing, as members of the Committee, Sir W. E. Smith, C.B., chairman, and Professor J. J. Welch, of Armstrong College, Newcastle, and also Mr. J. Foster King, Chief Surveyor to the British Corporation for the Survey and Registry of Shipping, Glasgow.

The papers which Mr. Baker presented to the spring and autumn meetings of the Institution of Naval Architects have brought him the Gold Medal of the Institution, and the work done in the Froude National Tank is highly appreciated everywhere. The tank tests made have involved speeds ranging from 21 ft. down to 0.6 ft. per second, and reliable results have been obtained over this range. The carriage track was tested for level, and was found to be very good over the central 300 ft. The amount of water lost in the main tank was 15,000 gallons per quarter, against 18,000 gallons per quarter in the preceding year. The number of models or variations of models tested for various bodies has risen to 101 during the fifteen months ended March, 1914. Of these, 75 were models for shipbuilders (against nine in the previous year); they varied in character from very full vessels having a prismatic coefficient of 0.8, and speed of 10 knots, to destroyers to be tested at 45 knots, and from broad and shallow river vessels to long and deep ocean passenger ships. In many cases considerable reduction in power—in one instance amounting to 25 per cent.—has been realised by the firms acting on suggestions made by the Tank Department that modifications of the model should be tried; quite a number of vessels are now being built whose lines were settled in connection with the tank tests, and two such vessels have made highly satisfactory maiden trips.

The busy work in the large tank has delayed work in the small tank on screw-testing apparatus. But the electrical details for the model screw drive are ready, and experiments on wake and hull efficiency with twin and single screws are being started. The screw models, 4 in. to 10 in. in diameter, are now cast in the tank building from a type metal, lead containing some bismuth; the moulds consist of plaster of Paris mixed with some



FIGS. 1 TO 7. TESTING BRAKE LINING.

lime. The addition of bismuth to the lead prevents the metal from expanding and destroying the delicate moulds.

Hydro-Aeroplane Floats.—The original apparatus for testing hydro-aeroplane floats could only be used for lift and resistance tests. In order to determine the tipping moment of the water forces on the float, to reduce the air resistance and to improve the balance, the apparatus, of which Fig. 8 is a diagram, has been devised. The float is suspended on ball-bearings B by a light aluminium carrier, itself suspended from the rear swinging arm A of a parallel motion erected at the centre of the towing carriage; A rests on knife-edges K, which in their turn are suspended by fine wires which are taken over the pulleys P and are loaded at W. The arm A is therefore free to move vertically in the guides T by an amount measured on S, and the load on the float can be varied. At the fore end of the carrier is a rigid graduated arc having its centre at B, in which a stop can be clamped in any position; this stop engages with adjustable jaws attached to the horizontal frame C, thus allowing a small angular movement (of a quarter of a degree each way usually) from the mean position. The small inclination of C to the horizontal is found by trial and error for any particular speed and angle, and in this way the float can be maintained at any angle to the horizontal. The couple

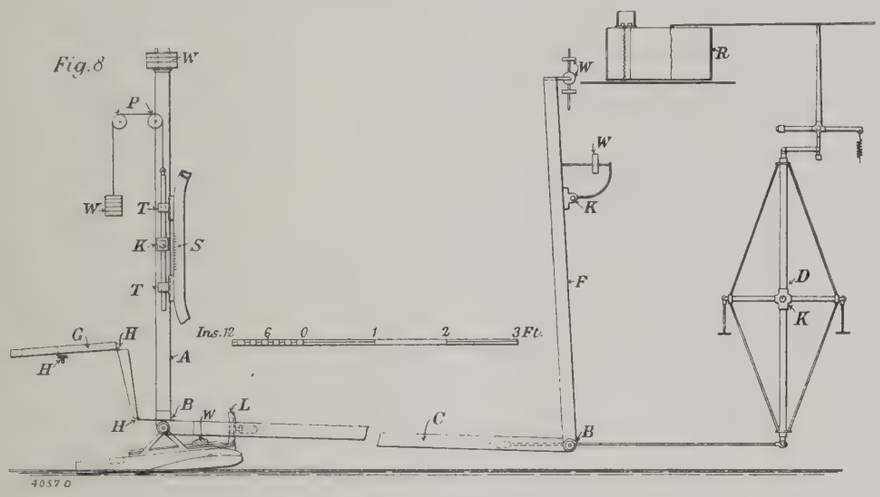


FIG. 8. TESTING HYDRO-AEROPLANE FLOATS.

on the float is measured by means of movable weights on the float-frame, which are adjusted during the run until the stop is just midway between the jaws. The towing force is applied at the fore end through a loose connecting-rod over to the dynamometer D, which records on the drum R; G is a guide-frame, H are hinges, and W is a sliding weight on the float. All the swinging parts being balanced in the air, a slight correction of the force is needed when the float is in water and A slightly out of the upright. A correction has also to be made for the air resistance, which is very small, however, owing to the shape of the struts and the effect of the balance-arm.

Research Work.—The completed research on the resistance of ships and the relation of the position of the humps on the resistance curves to the form of the model was brought before the Institution of Naval Architects by Mr. G. S. Baker last summer, and his remarkable paper was published in our issue of July 25, 1913. The second investigation concerns the question of the longitudinal distribution of displacement in a vessel of the ordinary mercantile type. The twenty models tested had all the same ratios of beam to draught and length to beam, and the same form of mid-ship section; the prismatic coefficients ranged from 0.59 to 0.83, and the parallel body made up 10, 30, 50 per cent. of the ship. In the recent experiments the models have been made without any parallel body at all. The experiments demonstrate clearly to what extent the bow or stern may be filled out not to pay a heavy penalty in high resistance. A particular point studied is the eddy formation at the stern, which affects both the resistance and the efficient working of the propeller. Perfect stream-lines at the stern, it would appear, are only possible if the stream-lines in closing round the ship are only required to move at an angle greater than 15.6 deg. to the line of motion of the ship, and the fullness of the stern should not be increased to an extent to make the prismatic coefficient of the after body exceed 0.75, except in cases of ships of small beam; but even in these cases great care is advisable. The work proposed comprises investigation of the manœuvring power of rudders of various shapes, and the measurement of the torques upon the rudder-heads, and further, the effect of passing ships upon each other. The wave-formation round models is to be studied in the small tank.

Metallurgy and Metallurgical Chemistry (Superintendent, Dr. W. Rosenhain, F.R.S.; Messrs. J. Murdock, A. L. Archbutt, Guy Barr, W. H. Withey, A. Marks, L. L. Bircumshaw, J. D. Grogan, T. E. Rooney, A. J. Turner, D. Ewen, J. L. Houghton, N. P. Tucker, P. G. Ward, and D. Hanson).

Machines, Apparatus, Ventilation.—The equipment of the Wernher building has been facilitated by a donation of 1000*l.* from the Goldsmiths' Company. Among the new machinery installed is a 30-ton tensile, compression, and bending testing-machine by Messrs. Amsler Brothers, of Schaffhausen, worked by a belt-driven three-throw oil-pump delivering oil to the ram of the machine, which has an extra long stroke. The pressure of the oil behind the ram, and thus the stress applied, is measured by a dead-weight pendulum manometer, to which the oil pressure is transmitted by a small piston. For rotating this piston the makers had supplied a handle and belt; but as the turning of the handle is jerky and distracts the attention of the observer, Dr. Rosenhain has replaced the handle and belt by an electric motor and worm-gear. The new Martens ball-machine for Brinell-testing was made by the well-known firm of Louis Schopper, of Leipzig; the ball is only of 5 mm. diameter, and intended for loads of 1000 kg. As the water pressure of the Laboratory is not high enough for working this machine direct, the water pressure in a steel vessel is raised by the compressed-air supply of the Laboratory. The machine is also used for shearing tests and perforations of thin sheet metal, the pressure required for punching a hole being determined. The ventilation plant of the chemical laboratories had to be modified when the laboratories were extended, because the cast-iron blades of the high-speed fan, which was rather noisy, were corroded by the acid fumes, and the fan became much less efficient. The new fan has larger blades, about 6 ft. in diameter, but is run by the same motor ($2\frac{1}{2}$ horse-power) at lower speed, 200 or more revolutions; the fumes are, moreover, filtered before entering the fan, being passed through a chamber lined with glazed bricks, in which fragments of limestone are placed on a succession of glass shelves, a spray of water playing over the shelves.

The Leitz metallograph, mentioned last year, has proved convenient for rapid work at moderate magnifications, whilst for the highest class work at very low powers (up to 10 diameters) and at high powers, a Zeiss vertical camera and the old Zeiss metallurgical microscope are used, illuminated by a hand-fed enclosed arc of the Westminster Engineering Company; a set of Zeiss apochromatic objectives has been purchased. The hinged supports for microscopes, which disappear into receptacles beneath the table when not wanted, were noticed last year.

Cooling-Curves.—The arrangement for taking heating and cooling-curves in vertical furnaces has proved successful. The specimen is lowered into and raised from the furnace, and when the upper end of the furnace is made the heated end, convection currents do not cause trouble in furnaces of 5-in. diameter. The raising and lowering was first attempted by an electric motor; but no motor was regular enough in its pitch circle, and an oil piston-pump, comprising a large and a small tube, a steel piston and a steel needle-valve, is now used for moving an electromagnet up and down; this electromagnet pulls the counter-weight of the suspended specimen, which is thus itself moved. Further to increase the accuracy of the records, an engine-divided glass scale is substituted for the paper scale, and a Campbell bifilar galvanometer for large deflection is used. This need only be brought back at intervals of 2000 microvolts, once every forty, instead of, as formerly, once every four observations. With the now almost automatic method of recording adopted, the observer of the galvanometer has only to tap the key at every transit, instead of plotting the curves from the readings on a chronograph tape; the depression of the key causes a pen, which moves outward at a regular rate from a zero position, to mark the paper and then instantly to return to zero. The new curves are remarkably fine, certainly, and Dr. Rosenhain finds, in agreement with the Bureau of Standards, that the much-disputed point Ar is not a double point.

Alloys Research (Messrs. Rosenhain and Archbutt).—The tests of light aluminium alloys, so much wanted in aeronautics, are continued with all care on a very extensive scale. In order to ascertain whether these alloys really incline to disintegration, as is often alleged, a very large number of castings, both pure and intentionally impure, and of rolled bars, have been prepared in the Laboratory itself and in the foundries and mills of the Atlas Aluminium Works, of Birmingham, and the Melton Works, of the British Aluminium Company. Some 1500 test-pieces, rings of 3 in. diameter, bars of 6 in. length, and also complex castings (motor-cycle crank-cases) have been prepared and carefully machined, numbered and marked, without being engraved or stamped, simple test-pieces being likewise taken for measurement lest any changes should be overlooked in the complex specimens. The test-pieces are measured at intervals of three months for dimensions and electric conductivity by the aid of simple devices, optical levers, *e.g.*, made in the Metrology Department, which measure to $\frac{1}{1000}$ in. with a magnification of 80, the ends of the bars being especially finished for this purpose. So far no changes in dimensions have been discovered, and no evidence of warping has been obtained, although the specimens are kept in different conditions in ovens at 100 deg. or 40 deg. Cent., wet and dry, for instance, in order to imitate damp hot climates, &c. As it was undesirable to insert contact-plugs of other metals into the test-pieces lest the contact-surfaces be damaged by corrosion, these faces are wrapped with rubber tape, or, better still, with wick or cloth impregnated with a thick lubricating oil; both these wrappings stand 100 deg. Cent., and are easily removed for taking measurements. The electric conductivity measurements are made on a Kelvin double bridge, designed by Mr. Melsom, of the Laboratory, and made by Mr. R. Paul.

Experimental Rolling-Mill.—As the rolling and forging of these various aluminium and other alloys cannot, at ordinary mills, be adapted to the special varied objects of the Laboratory, the Laboratory has decided on erecting an experimental mill of its own, and this erection has nearly been completed under the superintendence of Mr. Jakeman. A steam-engine being undesirable, electric power was adopted, and, since the Teddington supply is by three-phase current, and the local power-station declined to have an occasional peak load of 150 horse-power on its mains, a Tudor battery of 120 cells has been installed, which allows of variation between 10 and 240 volts, and thus of speed variations in the motor and mill which would be out of question in works. The motor can also be run on the 100-volt light circuit. The two-high mill, which has been supplied by Messrs. W. H. A.

Robertson and Co., of Bedford, is driven by the electric motor through a belt; two sets of rolls have been installed for roughing and finishing.

The mill will also be very useful in the study of the ternary alloys of aluminium, copper, zinc, to which, in some cases, from 0.25 to 0.50 per cent. of magnesium is added; many of these alloys break up in the rolls, and the ordinary mills are unsuited for dealing with both these hard and soft alloys.

Strain at High Temperatures. Cohesion of Metals Melting-Point of Iron. Cathode-Ray Furnace (Messrs. Rosenhain, Ewen, Hanson).—Owing to Mr. Humfrey's leaving the Laboratory, the work on the effect of strain at high temperature, resumed by Mr. Ewen, has been delayed. The important results of the investigation on the intercrystalline cohesion of metals have been discussed at the Ghent meeting of the Institute of Metals, September, 1913, and elsewhere. The melting-point of iron is to be determined in a vacuum furnace, encased in a glazed earthenware vessel supplied by Messrs. Doulton, which has, with difficulty, been made air-tight by painting it completely with sealing-wax; the vacuum is produced by a high-speed piston-pump of Gaede. The furnace is double, on the cascade principle; the inner alundum tube, $\frac{3}{4}$ in. in diameter, is wound with molybdenum wire (British Thomson-Houston Company) the outer tube, 2 in. in diameter, is wound with nichrome or tungsten (Durain Company); temperatures of 1000 and 2000 deg. Cent. are to be reached in the outer and inner furnace. Outside the furnace is a shield of silica, and then the water-jacket, through which water is sucked under reduced pressure. As it is very difficult to produce and maintain a vacuum in a furnace containing porous materials, cathode-ray bombardment is to be tried in a large-size apparatus (silica tubes) for melting-point determinations, as has been done by E. Tiede; a sparking-coil for 3 kw., giving 16-in. sparks, has been supplied by the Sanax Intensity Company, London, for this purpose.

Etching Steel. Brittle Platinum Dental Wires (Messrs. Rosenhain and Haughton).—The new reagent for etching steel—ferric chloride containing a little copper and tin chlorides—was described on page 783 of our issue of June 5. At the request of the Royal Dental Hospital the brittleness, occasionally shown by the pins of platinum and its iridium alloys used for fixing teeth, is being investigated with the aid of Messrs. Johnson, Matthey and Co. Platinum turns brittle in smoky gas flames, chemists know, and it is thought that some gas effect might take place when the pins are embedded in pasty porcelain; the solder used might also cause the brittleness.

Road Board Laboratory. Textiles. Aeronautics. (Messrs. Rosenhain, Bircumshaw, Withey, Barr, Turner).—At the suggestion of Colonel Crompton the chemical and physical properties of pitch and bituminous substances, alone or bound with sand, &c., are being studied by the penetrometer and other methods; this work was begun by Mr. Bircumshaw in Mr. Crompton's laboratory, and the penetration is determined at a constant rate of speed. Micro-sections are also examined. Glass and textiles further claim much attention. The strength of linen can now be tested at any degree of humidity, disputes previously arising between contractors and purchasers having been traced to atmospheric humidity. Balloon fabrics seem best to be protected against atmospheric influences by metallisation, which is effected in the Laboratory by the Schoop process. The study of metallic crystals by Röntgen rays on the lines of Bragg is to be taken up. The work in the laboratories for metallurgical chemistry is in charge of Messrs. Murdock, Grogan, Rooney, Ward and Tucker.

Electricity. Fundamental Units (Mr. F. E. Smith). *Lorenz Apparatus.*—A large number of absolute measurements of resistance have been made on resistances nominally of 0.001, 0.002, and 0.01 ohm. The results, attained under conditions of unprecedented care, are in excellent accord, and the international ohm would accordingly have a resistance of 1 00052 ohm (10^9 cm./sec.), with a probable error of 4 parts in 100,000. The derived value for the length of a mercury column, representing 1 ohm at 0 deg. C., would be 106.245 ± 0.004 cm. This length is slightly smaller than the mean of previous determinations made by different scientists since 1882. According to an investigation, carried on in the Laboratory in 1908, of the secular changes of the old B.A resistance coils, there were changes in those coils in the period 1882 to 1888. Correcting for those changes, the agreement with the previous ohm values becomes better; yet all the previous values exceeded the value 106.25 (except those of Rayleigh and Sidgwick, 1883, and of Dorn, 1889), and some (Rowland and Kimball, Mascart, Kohlrausch, Duncan and Wilkes, V. Jones) even exceeded 106.30. According to the new measurements, the length of a mercury column having the resistance of one international ohm is 106.30 cm. The mass of this mercury column is 14.4446 grammes. The diameters and axial lengths of the coils of the Lorenz apparatus were re-measured in 1913 and found to agree with the measurements of 1912 within 1 in 100,000. A very slight periodic variation in the pitch of the coils was, however, discovered, due to the leading screw of the lathe; this has to be allowed for by calculations. The coils increase in diameter when under current, and the discs, which rotate in the coil gaps, also increase in diameter. The former increase had previously been determined. To measure the latter, contact points were fixed on the stationary brushes which rest against the rim of the disc; the brushes, it will be remembered, resemble fiddle bows fitted with wire strings; a micrometer was turned until it just touched the contact, when a telephone sounded.

Current-Weigher. Resistance Standards.—In the absolute measurements by means of the current-weigher, the current is either kept constant and its value is calculated from the weight wanted to maintain equilibrium, or the current is varied and its mean value is calculated from the change in the period of the balance. The apparatus is less well suited for the latter method than for the former, but some determinations have been made, correct probably within 1 in 10,000. A disturbing feature in such apparatus is sometimes that the paraffin insulation does not always keep constant, owing to a slight acidity; it has in this case gone down from 1000 to 50 megohms. Two mercury standard resistances have been erected, each being filled three times. Most of the manganin resistances behave excellently, but a few have proved decidedly inconstant, the material being apparently faulty. The exchange of eight sealed manganin coils of 1 ohm with the National Institutions at Paris, Berlin, St. Petersburg and Washington has resulted in a very gratifying international agreement; the Teddington coils changed their resistance by 2 in 100,000 during their absence from the Laboratory, but the changes seem to have been gradual.

Magnetometer. Magnetographs.—The intended electrification of the South-Western Railway passing through Teddington has put the Laboratory on its guard, and a clause has, with the assistance of the Treasury, been inserted in the Act, in accordance with which the company undertake that the magnetic disturbances produced thereby at the Laboratory shall not exceed their present value—there are electric trams near the Laboratory—by more than 20 per cent. Any such disturbances would seriously affect precise electric measurements, and a non-magnetic hut has been constructed in the gardens of the Laboratory grounds, as far away from the buildings as possible, for keeping observations and also for conducting experiments, testing compasses (formerly done at Kew), &c. The hut was designed by Mr. Jakeman, and is built entirely in wood and Keen's cement, which is a kind of plaster, but has to be lined with asphalt to keep the moisture out; all concretes and cements proved hopeless, as they contain iron silicates. The hut is 30 ft. by 16 ft., and has a clear height of 9 ft.; a movable partition divides it into two parts. The new magnetographs of Mr. Smith are suspended by one quartz thread; the sensitiveness depends upon the torsion, and may be made very high by making the angle of twist, usually about 5000 deg., very large, up to 100,000 deg.; the weight of the magnet system, together with the aluminium vanes and the mirror, to which the magnets are attached, can be varied from 0.6 to 50 grammes. The apparatus, which have been constructed in the workshop, are inexpensive, and have, by overdamping, been made to trace the general trend of the horizontal intensity curve, without being affected by sudden fluctuations due to the disturbance from the tram-lines, which do not exceed 5 γ, as a rule ($1\ \gamma = 0.00001$ c.g.s. unit). We referred to these remarkable curves in our notice of the Royal Society soirée of last May. The new magnetometer, also made in the workshop, was suggested by Dr. A. Schuster, who has made a donation of 100*l.* for this purpose; the instrument allows of taking absolute measurements within four minutes; the principle is that the horizontal component of the terrestrial field is compared with the field produced by a current flowing through a coil.

Standard Cells.—The equilibrium in the Weston cells and the hydrolysis of mercurous sulphate in particular are still under investigation. Mr. Smith points out that when hydrolysed and non-hydrolysed salts are in contact with solvent and mercury, the mercury acts as a catalyst. He studies the solubility of mercurous sulphate in water by electrolytic titration—that is to say, by measuring the electromotive force of a cell as the titration proceeds, and noticing the sudden change accompanying the disappearance of the mercury ions.

General Electric Measurements (Messrs. A. Campbell, D. W. Dye, H. C. Booth). *Power Factors of Condensers. Wave-Meters. Inductance.*—The experiments on power factors of condensers have been continued up to frequencies of two million periods per second, thus covering the radiotelegraphic range, and castor-oil, first trusted as di-electric, comes out badly. At 800 periods its power factor is but 0.0005, but at one million periods it is enormously larger—0.038, so that, convenient as castor-oil is for small condensers in general, it cannot be recommended for radiotelegraphic work. Petroleum behaves much better, and mica also, though Mr. Campbell found that its temperature co-efficient was very small between 5 and 30 deg. Cent., but not constant. Castor-oil is undesirable likewise for the large temperature co-efficient of its capacity. He demonstrated this by a simple experiment; he passed currents through two wires, cooled the one in air, the other in castor-oil; the two currents were first of the same order; but as more cells were thrown in, the current through the air-cooled wire became a hundred times the stronger. Characteristic phenomena were also observed when a current gap was produced between two wires immersed in oil; the oil boiled finally, and when the current was slowly raised, the oil column looked like the striated gas column of a discharge tube. Three mutual inductometers have been constructed; the first reads up to 2 millihenrys, and is intended for ballistic galvanometer iron tests at 25 amperes maximum. The second is of 1 microhenry, and to serve for testing nominally non-inductive coils. The third instrument has a range of 4 henrys, and has in bridge measurement of secondary X-ray coils been used to measure up to 2000 henrys. In the wavemeter-room more than 350 coils have had their constants determined, some for wavelengths of 6000 metres. By the aid of a Duddell singing arc and tuning-forks commercial frequency meters are calibrated from 300 up to 800 periods.

High-Frequency Shunts and Resistances.—At high frequencies the self-inductance of a shunt turns out, as was to be expected, to be much more important than its resistance. The time constants of the instrument shunted and of the shunt should be the same for proper working. In the resistance decrement measurements the power spent by a given current in the coil is measured; a thermo-junction is placed on the coil, and the temperature rise, as well as the cooling curve, after switching off are determined. This method confirmed the interesting discovery of Lindemann that a solid conductor behaves at certain frequencies better than a stranded conductor.

Magnetic Tests.—The experiments on the bad effect of temporary, though moderate, strain on magnetic permeability were mentioned last year; the same amount of distortion, when made permanent by passing the limits of elasticity, does not lower the permeability so much. In applying the isthmus method it has been found practical to reverse the magnetising current instead of reversing the test-piece suspended in the gap. The permeability of iron wire and strip, used for lapping telephone cables, in order to increase their inductance, is tested both with rings of the material (by ballistic or other method), and with the lapping in position on the cable, by measuring the inductance; the two methods should agree; stalloid (silicon-iron) is recommended for the lapping. A small iron-core transformer of Mr. Campbell's, containing several flat rings of silicon iron, proved trustworthy at the highest frequencies (two millions), which is very astonishing. The research on the insulation resistance of silica and glass at high temperatures was brought before the Physical Society last August.

Aerials.—Several aerials have been put up; on

one of these the time signals from Paris and Norddeich are regularly received by the Horological Department (Metrology). The aerial is stretched over the ground in a length of 250 m. at a height of 7 m. to 12 m.

Electrotechnics (Messrs. C. C. Paterson, E. H. Rayner, M.A., A. Kinnes, B.Sc., B. P. Dudding, J. W. T. Walsh, B.Sc.).—Routine testing has absorbed 45 per cent. of the time of the staff. Most of the work done is confidential until the publication of the reports.

Photometry. Unit of Light.—The past winter was too mild again to secure very low values of atmospheric humidity for the realisation of the pentane unit (and its humidity coefficient) in terms of the values of electric sub-standard lamps. The intercomparison of the high efficiency standards of the principal national institutions has been concluded, with gratifying results. The final ratios are: Reichsanstalt / 0.9 × N.P.L. = 1.000; Bureau of Standards / N.P.L. = 0.997; Laboratoire Central / N.P.L. = 0.998. The comparisons entailed a colour difference corresponding to that between a carbon lamp at low efficiency and a 1.5 watt tungsten lamp (per mean horizontal candle). These latter photometric standards prove very reliable. Observations on 5.5-watt and 1.5-watt lamps are made with the aid of a flicker photometer. That a high accuracy can be obtained in colour-matching has also been demonstrated by the experiments in which electric sub-standards are measured against black-body radiations from fusing metals. The carbon filament and the tungsten filament have the same black-body temperature for the same colour match, but the specific consumption is, of course, much lower in the latter case.

Navigation and Motor Head-Lights. Factory-Lighting. Illumination Commission.—The research on navigation lights for the Navy, tests of burners, lenses and coloured screens, has been completed, and modified instructions are to be issued by the Board of Trade. The research on dazzling motor head-lights has several times been referred to in our columns. The driver wants the light to be thrown on the road, but the glare on the driver's right-hand side should not rise more than 3 ft. above the road-level, if the public are not to be inconvenienced. These objects can more easily be attained with head-lights of the mirror and lens types than with those of the parabolic type. The introduction of louvred glass fronts, built up of horizontally-arranged slats of glass, which throw the beam down, is to be welcomed. We also described last year the experimental room, 20 ft. by 12 ft., for studying factory-lighting at illuminations from the lowest values up to 20 ft.-candle. Dr. Glazebrook is chairman of the Home Office Committee on Factory-Lighting. Trials have been made with practical workers sitting at different tables, and Mr. Walsh, of the Laboratory, has taken measurements in works. The International Illumination Commission held its first meeting at Berlin in September; Mr. Paterson is secretary, and the bureau is at the National Physical Laboratory.

Special investigations have been conducted concerning the matt white cards serving as reflectors in photometry, and concerning the half-watt lamps containing tungsten filaments in nitrogen under high pressure.

Electrotechnics. Power Measurements.—The very important testing of alternating-current meters and watt-hour meters, on which Messrs. Paterson, Rayner, and Kinnes reported to the Institution of Electrical Engineers in May, 1913, is further being improved and facilitated in various ways. Resistance-boxes of higher values, self-calibrating (being balanced against one another), are used. In order to test three-phase wattmeters with their current and potential transformers under the conditions as they are used in practice, a switch has been constructed to earth the two mains in succession on 20,000-volt circuits, so that the wattmeter may be changed over from one measuring phase to the other, which is required for the two-watt-meter method; the switch is manipulated by wires from the stand at which the Kelvin static voltmeter readings, &c., are taken. A bifilar suspension has been given to this voltmeter to stop the "creep," which is hardly appreciable under ordinary circumstances, but troublesome with the fifty-fold magnification adopted; at the same time the moving system has been made of a light aluminium alloy, containing 25 per cent. of copper and 5 per cent. of zinc. The standard water-tube resistances, which answer very well, have been supplemented by 1½-in. tubes for 500 and 2000 amperes. The new motor alternator of Messrs. Crompton is very convenient for expeditious testing. It consists of a 25-horse-power continuous-current motor and a rotating field alternator; on to the shaft of the set is coupled one of the original Siemens alternators (5 kw.) feeding the voltage circuits, while the new alternator feeds the current circuits through step-down transformers. The field of the voltage machine can be shifted in relation to the current machine in the usual way; a heavy fly-wheel and copper discs running in the mercury pools for leading in the currents steady the currents.

Ebonite. Heating Tests of Field-Coils. Radio-telegraphy.—The pernicious effect of light on ebonite has been studied for the Admiralty. Mr. Rayner's work on the heating of field-coils has been resumed with coils especially wound by the British Thomson-Houston Company and by Messrs. Siemens Brothers; the results show that it is advantageous to impregnate coils of cotton-covered wire after winding, whilst the use of a protective covering of tape may increase the internal temperature by 15 deg. Cent. As secretary of the Advisory Committee of the Postmaster-General on Wireless Telegraphy, Mr. Rayner has visited the stations at Cullercoats, Clifden, Berlin-Nauen, Copenhagen and Hanover, and the erection of a research laboratory for radiotelegraphy in connection with the National Physical Laboratory is planned.

Direct-Current and Resistance Measurements (Messrs. S. W. Melsom, and H. C. Booth).—The test-work has much increased. The question of the unreliability of ebonite exposed to light has come before this department in connection with the ebonite tops of the boxes for resistance coils. The coils are now placed in brass boxes filled with oil, and are connected with the terminals and the mercury cups, both nickel-plated and varnished to withstand the creeping of mercury, on the top; the insulation between the cups and the top of the box is amberite; inside the box ebonite washers may safely be used.

Conductor Rails. Electric Cables.—The conductivity of conductor rails is generally stated in terms of standard copper or of Matthiessen's copper value, and misunderstandings arise as to whether copper and steel are compared as to the same length and weight, or as to the same length and sectional area. Since steel rails are bought by the number of pounds per yard, the comparison should be made accordingly, and the resistance be expressed in ohms. The question is occupying the Engineering Standards Committee. So far as the work at the Laboratory goes at present, the resistance of steel rails seems to vary directly, and the temperature coefficient inversely, with the total contents of impurities; the observed resistances in microhms per 100 lb.-yard varied from 13.9 (electrolytic iron) to 20.5 for conductor rails; an ordinary rail gave 25.3 microhms. The work for the Wiring Rules of the Institution of Electrical Engineers has made good progress, and the research on the heating of buried cables is now well in hand. Inquiries have been sent to fifty electricity-supply authorities; Mr. Melsom has visited various stations, and automatic temperature records of feeder-cables will preliminarily be taken.

(To be continued.)

METALLIC PERMANENT-WAY.—The exports of metallic chairs and sleepers from the United Kingdom for the five months ended May 31 were 48,313 tons, as compared with 53,961 tons in the corresponding period of 1913, and 46,549 tons in the corresponding period of 1912. British India takes the largest share of our exports of metallic permanent-way, having absorbed 39,382 tons in the first five months of this year, as compared with 40,202 tons and 36,679 tons in the corresponding periods of 1913 and 1912.

GERMAN RAILS.—The deliveries of German rails in the first five months of this year compared as follow with the corresponding deliveries in 1913:—

Month.	1914 Tons.	1913 Tons.
January	211,390	229,821
February	214,567	229,856
March	206,325	232,437
April	199,139	234,252
May	231,072	237,101

The aggregate deliveries for the first five months of this year were accordingly 1,062,493 tons, as compared with 1,163,467 tons in the corresponding period of 1913. It will be observed that the May deliveries showed more steadiness and approximated closely to the corresponding movement in May, 1913.

CATALOGUES.

Winding-Engines.—We have received from Messrs. Andrew Barclay, Sons and Co., Limited, Caledonia Works, Kilmarnock, Scotland, a catalogue section illustrating some of the principal types of winding-engines they have been building during recent years. The illustrations show engines of the coupled-cylinder type, fitted with drop, Corliss, Cornish, or slide-valves, and having either cylindrical or conical drums. The firm's auxiliary foot-brake for winding-engines is also illustrated and described in the catalogue, which forms a section of a new complete catalogue now in course of preparation.

Bearings.—The Berlin-Anhaltische Maschinenbau A.-G., of Dessau, Germany, have sent us a copy of their catalogue of "Bamag" economic bearings for machinery and line-shafting. These bearings are of the ring-oiling type, with either plain cast-iron or white-metal-lined bushes. Full particulars, with prices in marks, are given of open and closed pedestals with fixed or swivelling bearings, pedestals with water-cooled bearings, pedestals with sleeves for loose pulleys, thrust-bearings, open and closed hangers, wall-brackets, and pillar-brackets. Mr. C. A. Matthews, of 22, Bridge-street, Deansgate, Manchester, is the representative of the firm for the North of England and Scotland.

Fittings for Half-Watt Lamps.—The General Electric Company, Limited, of 67, Queen Victoria-street, E.C., have issued a pamphlet giving particulars of fittings specially designed for use with half-watt lamps. The intense brilliancy of these lamps, and the fact that they get much hotter than ordinary lamps, renders special ventilating and distributing arrangements necessary, and the long neck of the lamp has also to be concealed if artistic effects are aimed at. All these points have been taken into consideration in designing the fittings dealt with. Most of the fittings are equipped with the firm's special "Superlux" or "Equiluxo" glassware, experiments having shown that these glasses give the most efficient results, combined with very pleasing effects; other glasses can, however, be supplied, if desired. The pamphlet, which is fully illustrated, states prices and gives full particulars of a large selection of fittings for interior and exterior lighting.

Mercury Vapour Lamps, &c.—We have received from the Westinghouse Cooper-Hewitt Company, Limited, of 80, York-road, King's Cross, N., a number of pamphlets giving particulars of mercury vapour lamps and other apparatus manufactured by this firm. Among them are continuous blue-printing machines, water sterilisers, the "Rectigraph" photographic apparatus for copying drawings and documents, and a special type of silica lamp for laboratory use. These silica lamps are intended to form an efficient, reliable, and economical source of ultra-violet rays for use in scientific or industrial research work, and also to produce monochromatic visible light for spectroscopic work and polarimetry. The lamps are made in two distinct types. In one of these the tubes are very similar to those used for ordinary illuminating purposes, and are supplied with holders, so that they can be fitted up on an ordinary laboratory stand. Lamps of the other type have U-shaped tubes, so as to get the necessary length of arc in a small space. The tube is mounted on a marble base, which it overhangs in such a manner that the rays are not obstructed in any way. Each type is made in two sizes, rated for convenience according to their luminous intensity, which ranges from 1200 to 8000 candle-power; they are suitable for working at all usual voltages.

Turret Lathes.—We have received from the Judson-Jackson Company, Limited, 50, Marsham-street, Westminster, S.W., a pamphlet illustrating and describing the Schaerer patent high-speed full-swing combination turret lathes for chuck work of all descriptions. These lathes can swing 31-in. work in the gap and 22½-in. work over the bed. They have all-geared headstocks, giving twenty different spindle speeds, with only fourteen gears, all of which are hobbed from steel, and most of which are case-hardened. The number of feeds provided is twenty-four, and twenty-four screw-cutting changes can be obtained by means of a magazine-box; provision is also made for cutting coarse and odd pitches. The bed is of the box type, carried right down to the floor, thus ensuring great rigidity; it also forms a tank for cutting lubricant. The front saddle runs on slides cast on the front of the bed, the upper slide being of the V type, while the lower one, which is near the base of the bed, is a broad, flat, vertical surface. Special attention is called to the fact that cuttings cannot get on to any of the slides. The turret-saddle, which is exceptionally long, runs on two V slides, placed as high as possible in order to make the turret rigid. It is fitted with a power-driven quick-traverse motion, which works in both directions, and is automatically stopped at the end of the bed. Many other special features are referred to in the pamphlet, which gives a general specification for the machine, and illustrates its more important details; prices are also stated.

THE ITALIAN NAVY.—The Italian ironclad Christoforo Colombo, now in course of construction, will have a displacement of 26,000 tons, and will carry eight guns of the heaviest description, in four double turrets, and sixteen smaller guns. Two new ironclads have been commenced for the Italian Navy, and they are to be completed in three years. They are to steam at the rate of 25 knots, and power is to be developed exclusively from petroleum. Each ship is to be propelled by three screws, two of which will be worked by Parsons turbines, while the central screw will have a Diesel motor for cruising.

FOREIGN ENGINEERING PROJECTS.

WE give below a few data on several foreign engineering projects taken from the *Board of Trade Journal*. Further information concerning these projects can be obtained from the Commercial Intelligence Branch, Board of Trade, 73, Basinghall-street, London, E.C.

Spain: The *Gaceta de Madrid* announces that tenders will be received, up to July 13, at the Negociado Correspondiente del Ministerio de Fomento, Madrid, for the construction of new moles at the Port of Alicante. The time allowed for the work is two years, and the upset price is put at 832,219 pesetas (about 30,800*l.*). The notice contains a clause to the effect that at the first competition materials to be used will be confined, with certain exceptions, to products of Spanish manufacture, but that in the event of no decision being arrived at a second competition, in which foreign products may be accepted, will then take place. In the latter event Spanish products will have a 10 per cent. margin of preference over foreign.

Morocco: H.M. Chargé d'Affaires at Tangier has forwarded an extract from the *Bulletin Officiel* of May 22 containing a "Dabir" granting a concession to the Compagnie Marocaine de Fedalah for the construction and working of a public port at that place. Special provision has apparently been made for the work of construction being put up to tender. According to the *cahier des charges* annexed to the Convention for the concession, the works will include the construction of a jetty 200 metres (218 yards) long from the outer of the two islands in the bay, and the construction of wharves, "terre-pleins," a basin of 4 hectares (9.8 acres) area, and sheds and warehouses, the latter to be equipped with cranes, &c. The works must be finished within 15 months.

United States of America: H.M. Consul-General at Chicago reports that the State of Illinois intends to make strong efforts to improve the condition of its roads, and proposes to spend some 65,800*l.* this year on the construction of about 600 miles of hard roads throughout the State. In this connection an order for 1,600,000 sacks of cement has already been placed.

Mexico: The *Diario Oficial*, Mexico City, contains the text of a contract entered into between the Department of Agriculture and Colonisation and Señor Miguel Lanz Duret, representative of Messrs. Mengel Brothers, authorising the construction and working of four railway lines from the boundaries of the firm's concession in the Quintana Roo Territory as far as the River Hondo and Chetumal Bay, between the towns of Ramonal and Ubero. The concession is for a period of ten years, and the lines may be acquired by the State at the expiration of that period if desired. The *Diario* also contains the text of a contract entered into between the Secretary of the Treasury and Public Credit and Señor Enrique Fernández Castelló, for the partition and development of land reclaimed from the sea at Vera Cruz. The works specified include the construction of conduits, sewers, and mains for the drainage of superfluous and rain-water, and for the supply of drinking water, the construction of necessary embankments, and the paving of roads and footpaths.

FRENCH ROLLING-STOCK.—In the course of last year 121 locomotives, 96 tenders, and 4072 miscellaneous carriages and vehicles were delivered to the Northern of France Railway Company. The 121 locomotives comprised 25 compound six-wheeled-coupled engines, one compound locomotive, with five-coupled axles of the decapod type, 94 compound engines, with four-coupled axles of the consolidation type, and one compound locomotive, with three-coupled axles. Since January 1, 1914, further orders have been given for 43 locomotives and 1183 miscellaneous vehicles.

NORTHERN COAL, IRON AND STEEL COMPANIES.—We have received from the Business Statistics Company, Limited, of 20, Victoria-street, Westminster, S.W., a copy of a booklet they publish at the price of 1s. net, giving financial statistics of the various coal, iron and steel companies in the North of England. Two pages of the book are devoted to each company. On the first page are given a list of directors, the name of the secretary, the amount of capital and debentures, annual output, highest and lowest prices of shares during the past few years, and other useful information, while the second page is devoted to a summary of the more recent balance-sheet and profit-and-loss account; the profits made, dividends paid, sums placed to reserve, &c., during the past few years are also mentioned. The book, which it is proposed to issue annually in future, should thus prove very useful to investors.

CHILIAN RAILWAYS.—The Chilian Parliament voted last year a sum of 30,000 dols., to be given as prizes for the best designs of general railway works for dealing with the repair of 500 to 600 locomotives, 500 passenger carriages, and 6000 goods wagons. The first prize was to be 20,000 dols. and the second 10,000 dols. Messrs. the Niles-Bement-Pond Company, New York, took the matter up, and sent complete drawings showing the ground plan and elevation of every building; a plan of the yard, with tracks, yard cranes, paving, &c., complete; plans of the wiring, power distribution, central power-station and its equipment, the machine and erecting-shop, the machine-tools being in groups, one group for each item of the engine. The awards, we are informed, were made in the first week of June, and the firm named were awarded the first prize, the second prize going to a Belgian and English combine. It is expected that the shops will cost 3,000,000 dols.

THE PHYSICAL SOCIETY OF LONDON.

AT the meeting held on June 12, at the Imperial College of Science, Professor T. Mather, F.R.S., Vice-President, in the chair, a paper entitled "*Note on the Connection between the Method of Least Squares and the Fourier Method of Calculating the Coefficients of a Trigonometrical Series to Represent a Given Function or Series of Observations*," by Professor C. H. Lees, F.R.S., was taken as read in the absence of the author.

In view of the number of alternative methods which have been suggested for calculating the coefficients of the terms of a Fourier series to represent a number of observations of a variable quantity, the author points out that the Fourier method gives the most probable values of the coefficients, since it makes the sum of the squares of the errors at the points of observation a minimum.

Dr. C. Chree mentioned that the method was dealt with in Tait's "Natural Philosophy," but no proof was given. Professor Lees had supplied the proof, and the paper was of interest on that account.

Dr. W. Wilson (communicated remarks) said: Professor Lees deals with a function $f(x)$ of period l, whose values are given in the whole interval from 0 to l. In this case the validity and uniqueness of the Fourier expansion (provided $f(x)$ is subject to certain restrictions) have been demonstrated with complete rigour (Dirichlet, "Collected Works," vol. i., pages 133 to 160; and G. Cantor, *Journal für Mathematik*, LXXII.). It seems to me, therefore, that there is no question of the reliability of the Fourier coefficients, and the fact that the method of least squares leads to the usual Fourier expressions for the coefficients confirms the reliability of this method rather than that of the Fourier coefficients themselves.

A paper entitled "*A Magnetograph for Measuring Variations in the Horizontal Intensity of the Earth's Magnetic Field*" was read by Mr. F. E. Smith.

In the case of unifilar instruments for recording variations in H, if θ is the angle which the magnetic system makes with the magnetic meridian, M the moment of the magnet, and H the horizontal intensity of the earth's field, equilibrium results when $MH \sin \theta = T \phi$, where ϕ is the torsion of the fibre and T is a constant. In the instrument described ϕ may be made great or small, but high sensitiveness is secured by making ϕ great. The magnet system is supported by a quartz fibre, and critically aperiodic damping is obtained by means of an aluminium vane and two parallel damping plates. To diminish the sensitiveness the effective length of the fibre may be reduced. The general usefulness of the instrument is illustrated by photographic records, which show the instrumental peculiarities to be very small, and indicate that unless the system is aperiodic increased difficulty must result in the interpretation of the records. An over-damped system responds but slightly to rapid pulsations in H, but follows the slow changes which are common all over the world. The general sensitiveness of the records is about 3 mm. for a change in H of 0.00001 C.G.S. unit, but one record shows a displacement of 8 mm. for such a change.

Dr. Chree thought the instrument ingenious and likely to be very useful for the purpose for which he understood it was primarily intended—viz., the observation of the disturbances produced at the National Physical Laboratory by existing and prospective electrical tramways and railways. There were various features in the existing disturbances whose investigation seemed likely to be of interest and to the public advantage. There were also certain natural phenomena, for example, "pulsations," or small oscillations of magnetic force, for whose investigation the instrument from its great sensitiveness seemed well adapted, only for such purposes it would have to be set up at some station, such as Eskdalemuir, remote from London or any other large centre of electrical industry. There were, however, two features—viz., the somewhat rapid variation of scale value across the sheet, and the fact that the instrument responded sensibly to changes of declination as well as horizontal force, which, he thought, stood somewhat in the way of its employment for ordinary observatory purposes.

Mr. R. S. Whipple asked whether the author had considered the advisability of flashing a spot of light across the sheet to give the time scale, as was done at Potsdam.

Mr. C. W. S. Crawley considered the tramways were a great nuisance to magnetic observers. He had gone a good deal further in sensitiveness than the author, and even when situated 16 miles from the nearest tramways he had found them very troublesome. The little kick in the middle of the disturbance which Mr. Smith thought might be an instrumental error had often been noticed by him, and was a definite phenomenon in no way due to the instrument.

Professor T. Mather asked if the author had tried using the finest quartz fibre which he could handle. It appeared that the instrument took two or three seconds to attain its final position. If a finer fibre were used, a lighter and quicker magnetic system could be employed.

The author, in reply, agreed with the remarks of Dr. Chree. He had thought it would be interesting to set up an instrument to detect very small pulsations, such as might occur during solar eclipses, while neglecting the larger ordinary disturbances. He admitted that the variation of sensitiveness across the sheet would be a disadvantage to an ordinary observatory assistant, but it gave him no trouble whatever. In reply to Mr. Whipple, he had already started to employ the flash of light method for the time scale. In reply to Professor Mather, there was no doubt that the system could be made a good deal lighter if it were desired to measure very sudden disturbances lasting only a few seconds.

A paper entitled "*The Atomic Weight of Copper by Electrolysis*" was read by Mr. Albert G. Shrimpton.

Four copper cells separating two silver cells were run in series. The areas of the four copper cathodes increased from 10 to 50 s. cs. By plotting the weights of the copper deposits against the corresponding areas of the cathodes, and extrapolating to zero area, the weight of the deposit is corrected for under experimental conditions. The atomic weight of copper

$$= \frac{\text{corrected weight of Cu}}{\text{mean weight of Ag}} \times 107.88 \times 2.$$

The mean atomic weight for ten determinations = 63.563, with a mean error of ±.003. To obtain a uniform coherent deposit of pure metal the following points were considered:—

1. Cylindrical cells with stationary and rotating cathodes were used.

2. The cathode current density must be kept below a certain limiting value to prevent the formation of non-coherent deposits, due to secondary deposition. This was found to depend upon the geometry of the cell, the concentration of the electrolyte, the presence of acid and other impurities, the addition of a porous pot, and the rate of revolution of the cathode. Formulæ are given by which the limiting cathode current density can be found for all conditions of the cell for Cu, Ag, Au, and Zn.

3. To prevent the formation of loose crystalline clusters the current density must also be kept below a certain value depending upon the weight to be deposited. (Formulæ are given.)

Mr. F. E. Smith congratulated the author on the results of his work. He appeared to have triumphed over many difficulties, and for his particular purpose had converted the copper voltameter from an instrument of error into an instrument of precision. In future work he hoped that Mr. Shrimpton would avoid the use of common porous pots. They might produce trouble, and were not necessary, as all voltameter work could now be carried out without the introduction of any medium between anode and cathode. He should be pleased to give Mr. Shrimpton full particulars. The statement respecting deposition of hydrogen was, he thought, incorrect. It was not logical to assume that hydrogen ions were first deposited because of the lack of copper in the neighbourhood of the cathode, and then to state that as soon as they were deposited they went into solution again, and in doing so displaced copper from the solution. With regard to crystalline growths at the bottom of the cathode, he believed these were due to the high current density at the base due to the passage of the current through the liquid descending from the anode. There was also a possibility that the electrolyte was not quite pure. In the silver voltameter he had obtained striated deposits with impure electrolytes, but not with pure solutions. Mr. Shrimpton also stated that silver deposits from acidified solutions were normal; this was not his experience, nor that of other investigators. He believed the deposit to be less in mass when the electrolyte was acid. A rather important question arose with regard to any Cu_2So_4, which might be formed in the cathode space. Richards (who also extrapolated to zero area, as Mr. Shrimpton had done) remarked in his Paper: "A value obtained in this way must correspond to a deposit of copper slightly too great; for the mode of correction—*i.e.*, extrapolation to zero area—does not take account of the growing, although slight, presence of cuprous salts." Mr. Shrimpton said the extrapolation to zero area covered this case. The speaker thought the point was one that should be settled. Of course, when one reduced the area, the current density at the cathode was increased, and so also was the fall of potential near the cathode; this might have some influence.

Dr. J. H. Vincent mentioned that after working out the conditions necessary for satisfactory results, the author had performed the ten determinations quoted in the paper straight away, no results being rejected. As they all came within 1 part in 6000 of the mean, there appeared to be no doubt that the correct conditions for satisfactory working had been obtained.

Dr. S. W. J. Smith thought the author's views on secondary deposition could not be correct as they stood, although it was conceivable that sudden variations in the surface concentration of the copper sulphate, due to irregularities of convection, might make it possible for hydrogen to be deposited at one moment and to go into solution again at the next. Non-coherent deposits could be explained without invoking the aid of hydrogen. He thought the author's empirical conclusion that the limiting current density depends upon the concentration of non-ionised molecules had some theoretical support.

A paper entitled "*Note on an Improvement in the Einthoven String Galvanometer*," by Mr. W. H. Apthorpe, was taken as read.

BRITISH COAL EXPORTS.—The exports of coal from the United Kingdom in the first five months of this year amounted to 30,149,492 tons, as compared with 30,781,229 tons in the corresponding period of 1913. The expression "coal" includes also coke and briquettes. The principal exports to May 31 compared as follows with the corresponding exports in the first five months of 1913:—

Country.	1914. Tons.	1913. Tons.
Russia	1,304,074	1,442,564
Sweden	1,408,560	1,744,500
Germany	3,378,673	3,512,982
France	5,852,799	5,356,675
Spain	1,503,304	1,620,152
Italy	3,900,684	3,930,725
Egypt	1,425,024	1,303,316
Argentina	1,615,571	1,509,586

Upon the whole the exports have barely held their own thus far this year, the progress usually observable having sustained a check.

THE ALEXANDRA DOCK EXTENSION AT NEWPORT.

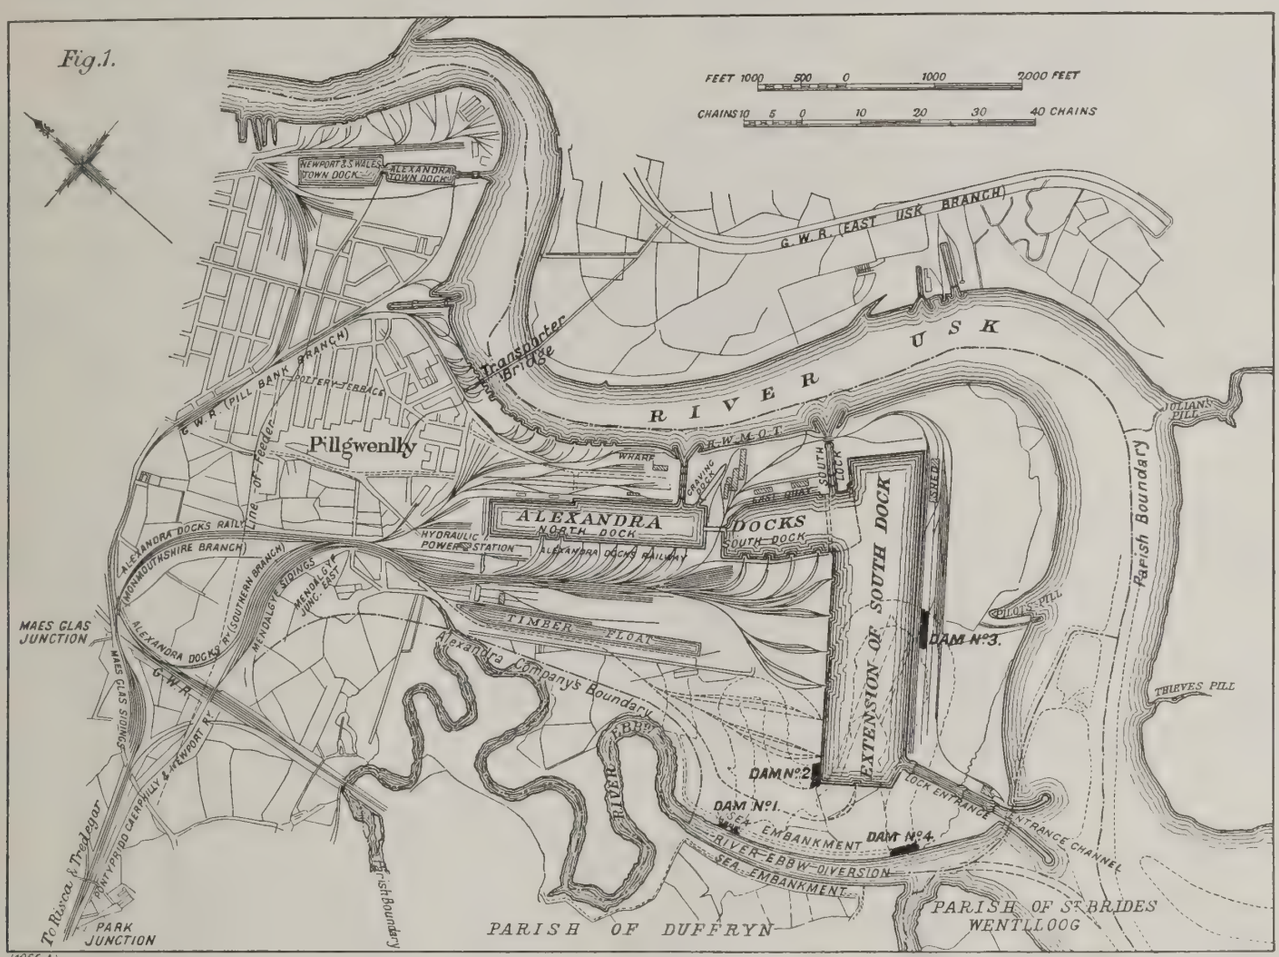
NEXT Tuesday will mark the culmination of a work which should do much to help forward the prosperity of Newport. On that day the latest dock extension and the new river entrance to the dock system will be opened by Prince Arthur of Connaught. Much of the work to be formally inaugurated has been in use for some time, the procedure adopted on the dock extension having allowed of the earlier part of the work being put into service before the completion of the later; but the bringing into service of the new lock forms a fitting occasion for a formal opening. This lock will greatly add to the utility of the extended dock, and will enable full advantage to be taken of its great area and depth, both by allowing a much larger type of ship to frequent the port than has been possible hitherto, and by increasing the facilities for ships of a more moderate size.

The trade of Newport is of a general character, and is by no means confined to coal, although, in view of the favourable position of the town in relation to the South Wales and Monmouthshire coal-fields, this latter commodity naturally occupies a prominent place in its exports. We believe that in coal exports Newport holds a position second only to one of the South Wales ports, and that in general cargo shipment it occupies the first place. Situated in Monmouthshire, Newport is geographically more favourably placed for handling trade to or from the Midlands than any of its immediate rivals, while it is in an equally good position as far as much of the South Wales coal-field is concerned. It is further situated on a river having an average width of about 1000 ft. and with one of the largest tidal ranges in the world, amounting to over 38 ft. at spring tides. This enables it to accommodate ships of large size and capacity. The new work that has been undertaken will enable even greater use to be made of these advantages than has been possible in the past, and should further establish the importance of the port.

The docks at Newport are the property of the Alexandra (Newport and South Wales) Docks and Railway Company. Those furthest up the river—the Alexandra, Newport and South Wales Town Docks—were constructed by an earlier company in 1842, and were purchased by the present owners some time after the construction of the Alexandra North Dock. The Town Docks are of 11½ acres, and are used for coal shipping and general trade. The entrance-lock is 200 ft. long and 61 ft. wide. The Alexandra North Dock, situated further down the river, as shown on the map given in Fig. 1, on this page, was opened in 1875. It has a river lock 350 ft. long by 60 ft. 9 in. wide, and is equipped with hydraulic coal-tips on one side and cranes and sheds for general trade on the other. The dock is 2500 ft. long by 500 ft. wide, and is connected to the South Dock by a channel 60 ft. wide, over which there is a road and rail swing bridge. The South Dock was opened in 1893. It is 1500 ft. long and 640 ft. wide, and has an entrance-lock from the river 503½ ft. long and 72 ft. wide. The dock is laid out with hydraulic coaling-tips on one side, and for general cargo on the other, on the lines of its neighbour, the North Dock. As will be seen from Fig. 1, ample railway accommodation is provided on the quays of both docks.

The extension of the South Dock, with which this article is more particularly concerned, lies at right angles to the old South Dock, as will be seen from the map, and with it forms virtually a single basin. The construction has resulted in a single dock with an area of 96 acres. Work on the extension was commenced in 1905, and, as has been mentioned, was so carried out that part of the new accommodation could be brought into operation before the completion of the remainder. The east end and some of the coaling-berths on the north side were first constructed and have been in service for some years. The west end, much of the south wall and the new southern entrance from the river, have only just been finished. The extension is 4000 ft. long by 1000 ft. wide, and has an area of about 76 acres. The average depth of water is 33 ft. The north side and west end of the dock are laid out for coal-handling, and four hydraulic hoists situated on the quay have been in use for some years. Three new hoists for high bunkering are now on order and will be situated two on the north quay and one on the west, in positions indicated by the railway connections shown by broken lines in Fig. 1. The south quay will be equipped throughout with cranes, sidings and sheds for handling general merchandise, the whole of these arrangements at the east end being already in service. The lock entrance is 1000 ft. long by 100 ft. wide and has a depth over the outer sill of 45 ft. at high water of spring tides, and 35 ft. at neap tides. A new electric power and pumping station has been built close to the new lock. Other new work carried out in connection with the estate has been the provision of a rolling road and railway bridge at the river end of the old South Lock, and the building of a ferro-concrete river jetty equipped with cranes between the north pier of the North Lock and the river coaling-jetties at Pillgwenlly. The whole of these works have been carried out to the designs and under the supervision of Messrs. Sir John Wolfe Barry, Lyster and Partners, with whom up to the time of his death the late Mr. C. A. Brereton was associated. The resident engineer was Mr. J. D. C. Couper, M. Inst. C.E., to whom we are much indebted for the assistance he has rendered in the preparation of this description.

Fig. 1.



The whole of these works have been carried out to

In describing the works, we will first deal with the general methods of construction of the dock and lock; then passing to the entrance jetties and to the lock-gates, and concluding with some account of the general machinery equipment. The construction of the dock, having been carried out in various stages, has been the subject of numerous contracts; but the whole of the work has been done by Messrs. Easton. Gibb and Son, of 9, Victoria-street, London, S.W. The site, as will be seen from Fig. 1, is bounded on two sides by the River Usk, and on one other by the Ebbw, a tributary of the Usk. The general level of the ground before work was commenced was some 7 ft. below present quay-level. The site was covered for a depth varying up to 40 ft. or so with a soft muddy clay, known in South Wales as "bungum." Below this there was a layer of gravel, overlying marl. The gravel was, in general, very hard and of good quality, but proved treacherous in places,

where beds of nearly pure sand were encountered. It was, in places, 20 ft. thick. The marl was of good quality, and gave a firm foundation wherever it was reached.

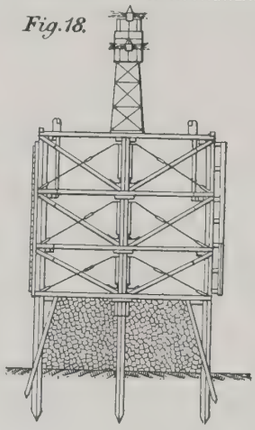
Fig. 2.

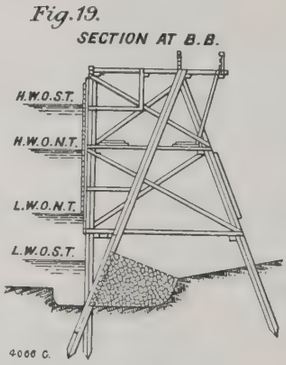
this work was in progress, excavation, chiefly by means of Ruston-Proctor diggers, was started at the eastern end of the dock. A bank of earth, the position of which is indicated in Fig. 1, was left between this excavation and the south wall of the dock, and was not removed until water had been admitted to the extension. A bank was also left on the left bank of the River Ebbw, shutting out its waters from the excavation. Concurrently with these two pieces of work a floating dredger was excavating in the old channel of the River Ebbw, removing material up to the line of a diagonal bank across the south-west corner of the dock, which is indicated by dotted lines in the plan. This bank formed a boundary of the dock, as it was constructed before the lock works were put in hand.

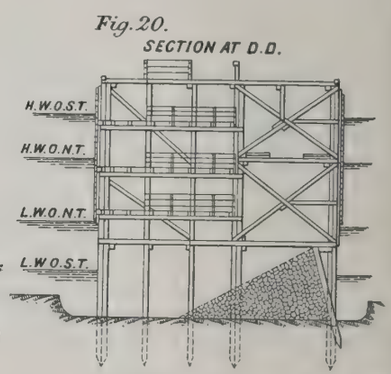
By the time this dredging in the Ebbw Channel was completed the excavation of the upper lift of dock was carried on in the dry. At the same time the eastern portion of the south wall was built. Water was then admitted to the extension, and the bank separating it from the South Dock was removed by means of a bucket-dredger. The dredged material was pumped ashore by means of a floating suction-dredger, taking the material from the barges, which were filled by the bucket-dredger. The material was dumped to the north-west of the dock extension, on the land to be covered by the railway connections to the new coaling-hoists.

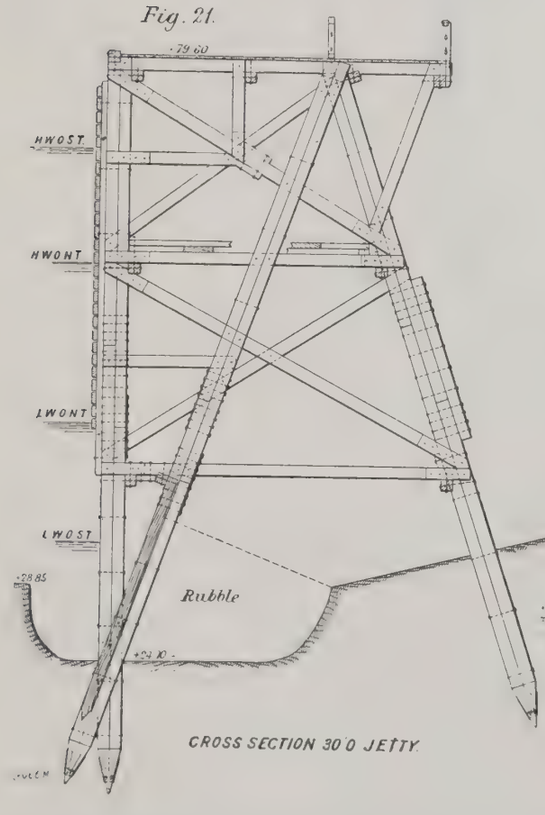
As the extension has a depth of water of 33 ft., and the South Dock one of only 30 ft., there is a step between the two. Its position is indicated by the double broken lines running across the South Dock from the north wall of the extension in Fig. 1. The work we have so far described completed the

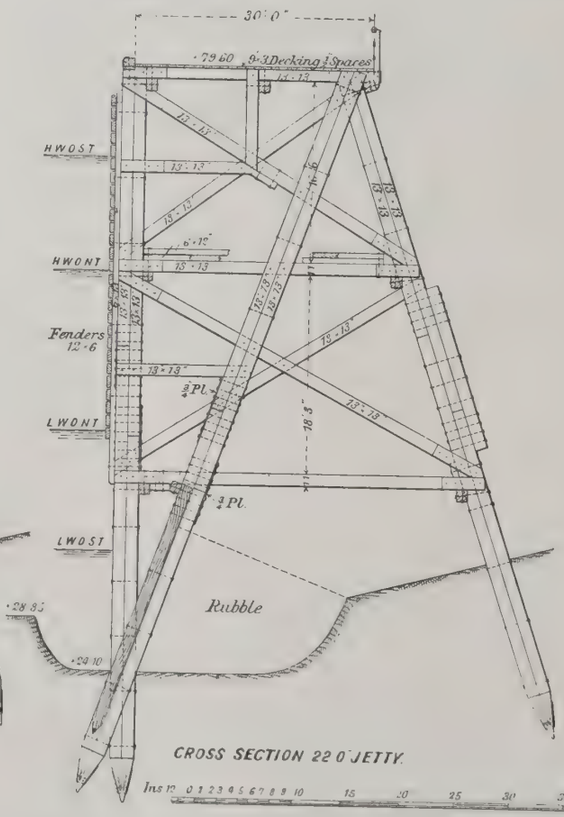
CROSS SECTION OF ROUNDHEAD.

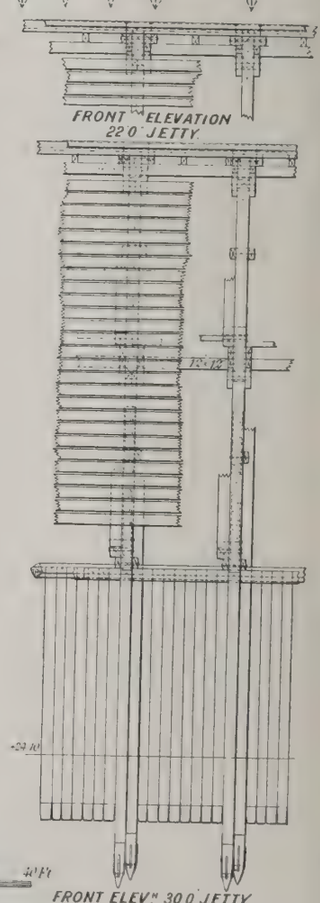












At the commencement of the construction of the dock, the River Ebbw meandered across the western end of the site, in the course indicated by broken lines in Fig. 1, and among the first work to be undertaken was the construction of the diversion channel well to the west of the position of the future dock. This channel was taken out in the dry mainly with a Lubecker land-dredger. The top lift only was removed in this way, and, in the first instance, banks were left at each end of the diversion, and no water was admitted. While the diversion had been finished, and the floating dredger was put to work to cut through the two ends of the diversion, and to take it out to its full depth. As soon as the two ends had been cut through, and while the deepening was proceeding, the old channel of the Ebbw was cut off by tipping-dams at the ends, as shown in Fig. 1. When dams Nos. 2 and 3 had been completed the portion of the old channel between them, crossing the site of the dock extension, was pumped out, and the remainder of the excavation of the dock as it was first put into service. The area of water available for use was roughly half that of the present dock, since, although the area indicated in the plan is rather more than this, the tapering west end was not all available for shipping, as the depth was insufficient beyond the fourth coal-hoist. This end was dredged out later.

Before proceeding to a description of the construction of the lock and south-east corner, which formed the subject of a separate contract, we may say a little more in detail of the dock as it was com-

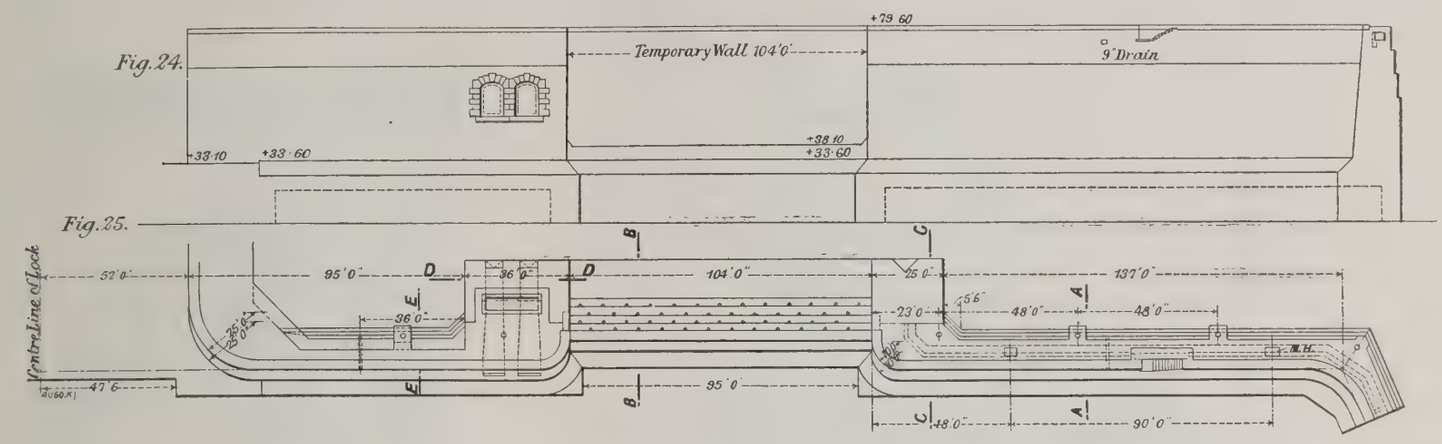
pleted up to the time we have now reached. The whole of the work put into the original extension was of a permanent character, and now forms part of the completed dock, except, of course, that the diagonal bank has been removed. The main work of excavation, as we have said, was done in the dry, and the banks were completed before the admission of water. The level of the bottom of the dock lay in general about 10 ft. above the gravel. The banks on the north side and the east end are slopes pitched with stone, obtained by the contractors from a quarry specially opened a few miles up the river valley. On the north side there are four hydraulic coal-hoists, and three more are on order. The hoists are carried on concrete piers, in connection with which some interesting work was done, but it will be better to defer detail reference to them until we deal with the coal-handling plant as a whole. We should say that, in general, surface tipping had to be resorted to to raise the land to quay-level, and that spoil taken from excavation was used on this work.

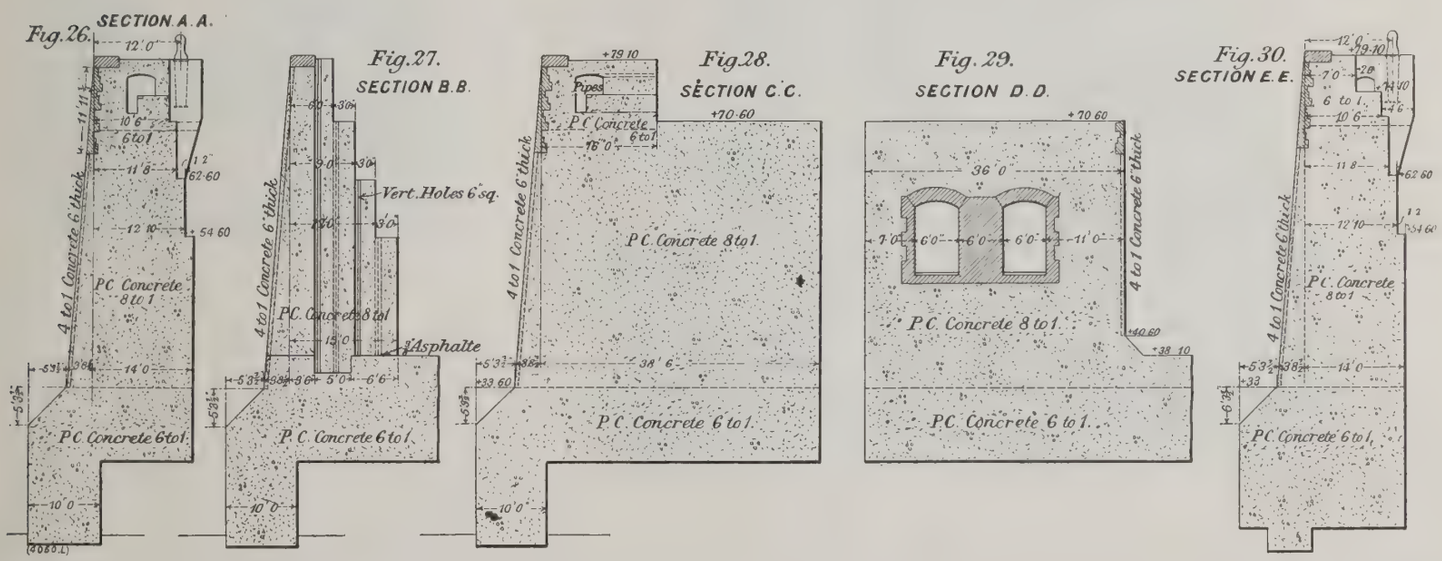
The only wall proper in the extension in its original form was that forming the south quay. It is of mass concrete resting on the gravel formation. The foundations were taken out in timbered trenches. A characteristic cross-section of the wall is given in Fig. 2, on page 34, from which it will be seen that a hard-stone filling was put in behind the wall, and the ground behind this made up with soft filling. A culvert for hydraulic pipes, electric cables, &c., runs through the upper part of the wall. Cast-iron surface drain-pipes are carried through the wall at 100 ft. intervals, while lower down the wall is backed with a rubble drain connected to the dock by weep-pipes. One of the most interesting features of the wall has reference to the carrying of the crane-road for the 6-ton hydraulic cranes which serve the quay. The arrangement is well shown in Fig. 2. The front crane-rail lies directly on the concrete mass of the wall, but the back one is carried by a 12-in. by 24-in. Hennebique ferro-concrete beam, which lies parallel with the quay-front. This beam is supported by 14-in. by 20-in. ferro-concrete struts, and 12-in. by 18-in. ferro-concrete ties spaced 10 ft. apart. The struts sit on one of the back steps of the wall. The whole arrangement was built in the air, and the stone-filling afterwards packed round it. A view during building is given in Fig. 31, on Plate XI. The construction is very neat, and while economical in material, gives an entirely satisfactory foundation for the cranes. This quay is equipped with a shed and railway-sidings at its east end for handling general traffic. We will, however, refer more in detail to these features when dealing with the dock equipment.

Turning now to the construction of the lock and the south-east corner of the dock, it will be remembered that the old channel of the Ebbw River, which crossed the lock site, had already been isolated by the tipping of dams Nos. 3 and 4. This channel was pumped out, and the excavation of the south-east corner of the dock proceeded in the dry, a bank being left to separate it from the earlier part of the extension which was in use. In the meantime a clay bank was tipped across the front of the site from Pilot's Pill to the left bank of the new mouth of the Ebbw River. This bank lay almost exactly over the high-water mark, which is indicated in Fig. 1, and formed the first or inner dam, under the protection of which the inner end of the lock and the western part of the South Quay wall were constructed. The east and west river banks were then tipped. These are the banks which form the present river boundaries and sweep north-east and north-west from the land end of the entrance jetties, as shown in Fig. 1. Some trouble was experienced with these river embankments owing to the action of the tides and the greasy nature of the foreshore mud, but satisfactory banks were finally obtained. The outer faces were pitched with rough stone. Before the river embankments were completed the tipping of a second temporary dam was taken in hand. This was formed round the outer end of the future lock. It formed approximately a half-circle in plan, and projected into the river a distance nearly halfway down the length of the future jetties. It joined up with the river embankments at its inner ends.

This second temporary dam was formed of rubble stone backed up with sand and clay, and when it was completed the construction of the outer end of the lock was taken in hand behind it. When the walls at the outer end of the lock had been completed, a third temporary dam was tipped inside the second temporary dam, cutting across the lock site about the middle of the length of the outer pen. The first temporary dam was then cut through, and the lock-walls in the neighbourhood of the middle gates were completed. A view of the inner compartment of the lock at this stage showing the invert trenches being excavated and the first temporary dam in the background is given in Fig. 32, on Plate XI. In the meantime a concrete monolith dam was sunk between the lock-walls outside the outer gate compartments, and when this was completed the portion of the third temporary dam between the lock-walls was removed. The dumpling of the outer portion of the lock was then excavated, and the invert put in. The inner and outer gate-chambers had in the meantime been completed. While the gates were being erected, the outer portion of the second temporary dam was removed by dredging, and the East and West river walls were completed up to the backs of the lock-walls. The building of the timber jetties was then commenced. When the gates were completed, water was admitted to the new corner of the dock extension and to the lock, and the removal of the monolith dam was commenced. The earth bank which had been left between the old and new parts of the dock extension was then removed by dredging.

In this brief sketch of the general method of procedure, we have, for the sake of clearness, omitted any reference to the details of the lock or of the method of building the walls. Referring to construction, in the first instance, we should say that all the wall foundations were taken out in





timbered trenches. The trenches for the South Quay wall, and parts of the side walls of the lock, were timbered with 2-in. vertical poling-boards. Where, however, the bungum was too soft for the use of poling-boards, the trenches were surrounded by half-timber or whole-timber sheet piling. Owing to the hardness of the gravel, the sheet-piling could only be driven into it to a depth of 3 ft. or 4 ft., and consequently poling-boards were used when excavating through the gravel below the sheet piles. In the case of the wider trenches, king-piles were driven at intervals of about 20 ft. on the centre line of the trench, and the trench was timbered with struts extending from walings fixed against the sheet piling to horizontal timbers running between the king-piles. As, however, the king-piles could only be driven a few feet into the gravel, they had to be lengthened when the excavation reached their points. The method adopted was to cut off the points of the king-piles with their shoes, and to insert short vertical timbers below them, secured by vertical flitches, thus lengthening them downwards as the excavation proceeded. The face of the gravel below the sheet-piling was timbered with 2-in. vertical poling-boards, as described above. This method of working proved perfectly successful, although the job was marred by one bad accident, in which the trench for the south-west wing wall of the lock fell in where some treacherous ground was encountered. This trench was subsequently surrounded by steel-sheet piling and successfully re-excavated.

Details of the lock will be seen in Figs. 3 to 10, on Plate X. It is one of the largest in the world, being 1000 ft. long and 100 ft. wide. The two pens are 600 ft. and 400 ft. long respectively. The depth of water on the outer sill at spring tides is 45 ft., and at neap tides 35 ft. Double levelling culverts have been constructed throughout, an upper and lower one in each wall. These can be seen in the cross-sections on Plate X., while their intakes are shown in several of the general views. Among these we may mention Fig. 33, on Plate XI., which shows the former in position for the upper culvert in the east wall of the inner gate-chamber. The view is taken looking north. Fig. 34, a view of the inner gate-chamber at a later date, shows the intakes very well. Fig. 35, on Plate XII., shows the multiple intake to one of the low-level culverts during construction, while Fig. 36, subjoined, is a view inside the levelling culvert of the new lock entrance. This view shows the grooves for the hand and hydraulic sluices, which we will refer to more in detail later.

A view of the inner gate-chamber, showing the gate-sills, roller-path foundations for the gates, and the forebay under construction, is given in Fig. 37, on Plate XII., while a view of the same chamber ready for the erection of the gates is given in Fig. 38. The sill-stones for the emergency caisson can be seen in the foreground. The laying of these sill-stones is shown in Fig. 34, Plate XI., already referred to. A view of the completed lock showing the culvert intakes on both sides is given in Fig. 39, Plate XII. A temporary footbridge, used during the completion of the lock, can be seen in this view. Two general views of the locks are given in Figs. 40 and 41, Plate XIV. Both these views are looking north. The former shows the invert of the outer compartment under construction, while the latter, which was taken from the top of the power-station chimney, shows the lock nearly completed. A feature of this work to which we have not yet referred is that the level of the water in the dock system is maintained at a higher level than the general high-water mark of the river. To enable this to be done make-up water must be supplied. In the old dock system the water was obtained from the Ebbw River at Bassaleg, a pipe-line being taken from it at this point to the north end of the North Dock. For many years, however, this supply has proved insufficient, and a pump was erected on the North lock pier in 1895. With the completion of the extension this supply in turn has become insufficient, and a new pumping station has been built and equipped as part of the new work. It is situated on the east side of the lock entrance and is indicated in Fig. 1. The plant of the station we will refer to later, but in connection with the construction of the lock we now draw attention to the 12-ft. diameter delivery culvert through which the power-station pumps supply water to the dock. This culvert, which is of cast iron for the greater part of the length, is embedded in the east wall of the lock. In can be seen in various stages of the construction of the lock in Figs. 40 and 41, Plate XIII. Fig. 40 is a view looking south-west, and shows the culvert dipping down to discharge its water near the bottom of the dock, Fig. 41 shows the culvert partly erected, while Fig. 42 is the trench for the east side wall of the middle gate-chamber.

Before dealing with the entrance-jetties, we should like to say something of an interesting concreting plant which was constructed and patented by Messrs. Easton Gibb and Son in connection with the building of the lock. This plant is shown in Fig. 46, on Plate XIV., and Fig. 47, subjoined. It consisted of a Smith mixer mounted on a travelling carriage which also carried the boiler and steam-engine for driving the mixer. At the top of the carriage there was a hopper divided into two compartments, each of which carried one charge for the mixer. At the back of the mixer there were two elevator skips worked in guides in such a manner that when one skip was discharging its contents into one of the divisions of the hopper at the top of the mixer, the other was at the bottom of the guides ready to receive another charge of material. These skips are clearly to be seen in Fig. 47. Behind the mixer-carriage, and running on a parallel line of rails with it, were two belt-conveyors driven by chains from the engine of the mixer. Over the belt-conveyors were fixed measuring-boxes for measuring sand and stone, and the conveyors, which were running continuously, discharged the stone and sand into whichever skip was in the lower position. One of the conveyors is clearly shown in Fig. 47. The sand, crushed stone, and cement were brought up on trucks on a third line of rails parallel with the conveyors. The wagons containing the cement, which was gauged into bags before being loaded, were placed immediately behind the mixer, so that the requisite number of bags could be discharged directly from the wagon into the skip. The sand and stone were unloaded by hand from the wagon into the measuring-boxes above the conveyors, and as each skip came into position to receive a fresh charge, the contents of the requisite number of measuring-boxes were allowed to drop through the bottom-opening doors of the boxes on to the conveyors, and the measured charge was thus conveyed to the skip. Meantime the requisite quantity of cement was emptied from the cement wagon directly into the skip. The positions of the wagons in relation to the conveyors when the plant was in operation is shown in Fig. 46.

The skips were raised from their loading position to the top of the carriage, and *vice versâ*, by a friction

winch worked by the mixer-engine. The full skip on reaching the top of its travel discharged its contents into one or other of the compartments of the storage hopper, one compartment of which thus always contained a charge for the mixer. The charge from the hopper descended through the door in the bottom of the hopper into the mixer, and the requisite quantity of water was added. The mixing was then completed, and the mixer tilted so that it discharged its contents into a chute which conveyed the concrete into its place in a trench. The chute can be seen in Figs. 46 and 47. For depositing concrete in the upper part of the wall above the level of the mixer the chute was raised to a sufficient height to allow the concrete to flow by gravity into position in the wall, and the mixed concrete was discharged from the mixer into a skip hanging on the front of the mixer-carriage. The skip was then elevated by means of a friction winch, and discharged its contents down the chute. Traversing gear was provided by which the mixer-engine could be utilised to travel the mixer from one position to another alongside a trench, and the belt-conveyors were secured to the mixer, so that they travelled with it. A great deal of work was done with this plant, which proved very convenient. It can be seen in several of the views of the lock under construction, as, for instance, Fig. 32, which shows the concrete being conveyed from the chute down the side wall of the lock in a distributing-pipe.

The river jetties, which are shown in the remainder of our present illustrations, do not require a great deal of comment, as their general lines and details will be seen from the figures, Figs. 11 to 23, on Plate X. and page 34. Fig. 11 is a general plan of the lock entrance showing the form of the jetties, while Figs. 12 to 17, Plate X., give details of the round-heads at their outer ends. Characteristic cross-sections of the jetties themselves are given in Figs. 18 to 20, on page 34, while Figs. 21 to 23, on the same page, show sections and details to a larger scale. The jetties are constructed of pitch pine throughout, and the piles consist of two 13-in. by 13-in. pitch-pine timbers bolted together and shod with a heavy cast-iron shoe, 10 in. square at the base, the points of the timbers being protected by steel plates, $\frac{1}{8}$ in. thick. This type of pile was adopted after numerous experiments, and it was found that by dredging away the superincumbent clay before the piles were pitched, it was possible to drive them down well into the gravel. They were driven by means of a 50-cwt. steam-monkey on an overhanging pile-frame which travelled upon the piles already driven. On the back side of the west jetty there is a landing-pier for passenger steamers. Each jetty carries twin harbour lights on light steel towers on the round-head. A new channel has been dredged from the lock entrance to the buoy which marks the mouth of the River Usk in the Bristol Channel. The narrowest bottom width of this channel is 650 ft., and it widens to 900 ft. opposite the lock. The depth is 42 ft. below high water of spring tides. A channel will also be dredged on the west side of the west jetty to give depth for steamers using the passenger-pier. This channel will not be deep enough for the conditions of the lowest tides, and when a steamer arrives at such time it will use the east side of the jetty, at which landings have been erected. This arrangement will not interfere with the use of the lock, as no steamer of large size will be entering or leaving it at the state of low tide at which passenger-steamers could not use the pier on the west side.

The land to the west side of the lock entrance has been reserved for a graving-dock, and a temporary wall has been put in in the wing-wall at the south-west corner of the dock. This wing-wall is illustrated in detail in Figs. 24 to 30, on page 35. The position of the temporary wall is clearly shown in Figs. 24 and 25. In addition to this wing-wall, provision has been made for the future graving-dock by the putting in of the necessary culverts connecting it to the power-station pumps and the main dock. The same pumps will handle the graving-dock water which handle the water from the river. A view of the front of the lock from the dock end is given in Fig. 43, Plate XIII. This shows the wing wall at the right-hand side with the intake culverts to the graving-dock. On the right-hand side can be seen the openings of the discharge culverts from the power-station. These culverts are carried down close to the bottom of the dock, as has already been mentioned. The idea is to prevent disturbance of vessels in the dock.

(To be continued.)

THE ROYAL AGRICULTURAL SOCIETY'S SHOW.

(Concluded from page 24.)

THE Eagle Engineering Company, Limited, of Warwick, exhibited several oil and petrol-engines, their latest type being illustrated herewith in Fig. 13. This is a petrol-engine, which has been designed principally for the New Zealand market, in which it has met with great success. It has a horizontal cylinder, with the inlet-valve above and the exhaust beneath at the back end. The petrol is led by gravity from the fuel-tank over the crank to a carburettor, near the back end close to the induction-pipe, which is fitted both with a valve for varying the air-supply and also with a needle-valve for the petrol. The mixture then passes into a short mixing-chamber, and thence is admitted to the cylinder through the inlet-valve. The inlet-valve is of the suction type, but it is also controlled by the governor, which also controls the exhaust; that is to say, the exhaust is opened, and the inlet positively held closed when an explosion has to be cut out, the governing being on the hit-and-miss principle. The governor is of the centrifugal type, arranged on the main shaft inside the flywheel. On this shaft is a cone, worked out and in by the action of the governor. If the cone is forced out by the action of the governor weights, a short lever connected with the hit-and-miss gear is pushed away from the shaft, the lip and striker engage, and a long lever running back to the engine-valves is held down. This holds the exhaust open and the inlet closed. This lever is movable sideways on its pivot, roughly midway in its length, and for half-compression for starting can be pulled out on its pivot, so that it works on a half-compression cam alongside the normal cam. The

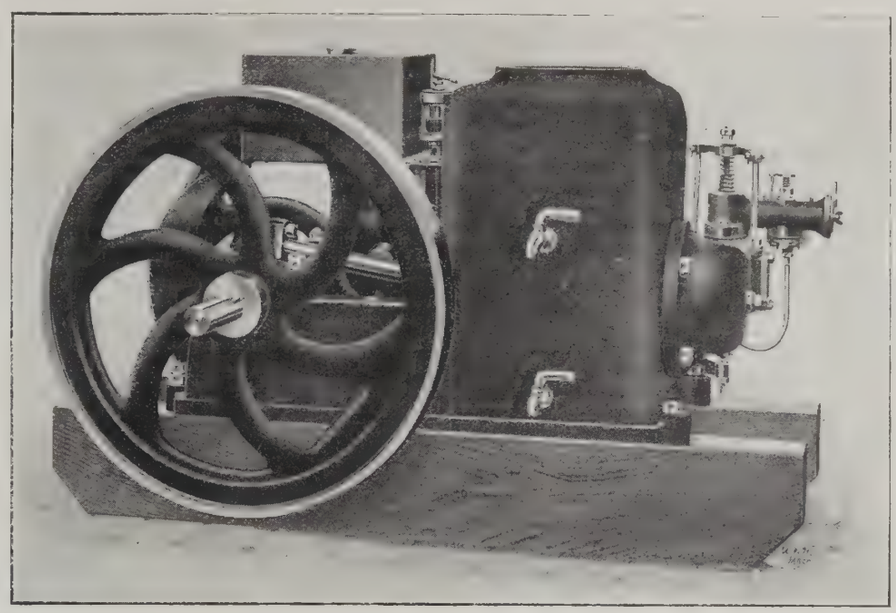

FIG. 13. 5½-BRAKE-HORSE-POWER WARWICK PETROL-ENGINE.

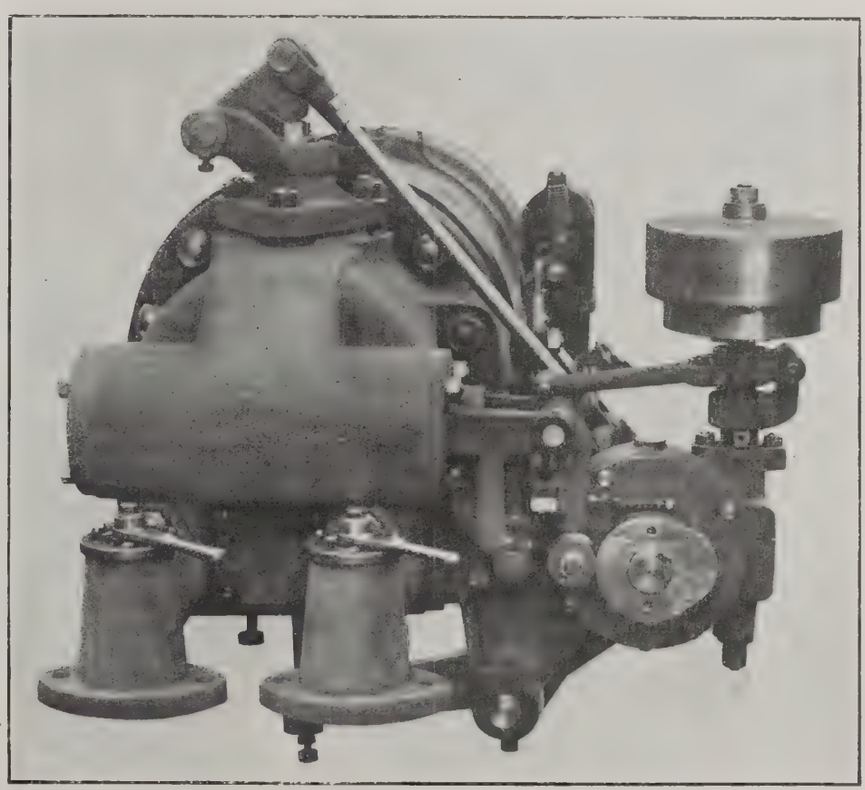

FIG. 14. GOVERNING-GEAR OF 54-BRAKE-HORSE-POWER FIELDING SUCTION-GAS ENGINE.

cylinder is fitted with a large box-shaped hopper-cooler sufficient for two to three hours' working at full load, provision being made for drawing off and changing the water if necessary. The cylinder-head is also jacketed, and a lead disc is fitted, so that in case of frost this should fail instead of the casting. The magneto is gear-driven.

A novelty was to be seen at the stand of Messrs. Thould and Hutchinson, of Upton-on-Avon. This was an engine constructed by Messrs. Hardy and Padmore, Limited, Worcester. It was an oscillating petrol-engine of about 5 brake horse-power. This engine, built to the Southall patents, was mounted on a diagonal frame, and was fitted with two fly-wheels and small driving-pulley. The cylinder had a bore of 5 in. in diameter, the stroke also being of 5 in. It works on the two-cycle principle, the air being compressed at the gland end of the cylinder, and then forced through a passage and port to the back end, on the port being uncovered by the piston. The compression is then completed at the back end. The cylinder is fitted with two trunnions, ground and fitting into ground bearings. Through the bearing and trunnion on one side the charge is admitted, a non-return valve being placed just outside the bearing. The exhaust is through the other trunnion. Magneto ignition is furnished, governing being accomplished on the throttle. Water from an overhead tank is led through an iron pipe to the frame, and thence to the cylinder by a piece of flexible pipe. The return to the tank is by a length of flexible hose. The engine has a speed of about 450 revolutions per minute. The two fly-wheels are 36 in. in diameter, and the whole plant weighs about 10 cwt.

We described the 45-brake-horse-power horizontal semi-Diesel crude-oil engine exhibited at the stand of Messrs. Fielding and Platt, Limited, Gloucester, in our issue of the 26th ult., page 872. This pattern of engine the firm is making in sizes ranging from 45 to 160 brake horse-power. The engine works on the ordinary four cycle, with great steadiness. This class of engine will use any liquid fuel suitable for the Diesel type of engine. Another new departure for Messrs. Fielding and Platt is a small pattern of vertical petrol motor, with two fly-wheels, and of 4 brake horse-power capacity. This little engine runs at 700 revolutions per minute, using 0.650 petrol. The engine is governed on the throttle. High-tension ignition is provided, and pump feed for the carburettor. The engine is substantially built and well finished, as would be expected in work by this firm. The firm also showed working one of their suction-gas plants, capable of being started up in 10 minutes, and to which we have referred on previous occasions in ENGINEERING. A 54-brake-horse-power Fielding suction-gas engine was working off this plant. This engine had graduated governing, with an explosion for every cycle, a feature which, it may be mentioned, ensures steady running and much better conditions for the suction-gas plant than the hit-and-miss system. A view of the back end of the cylinder-head is shown in Fig. 14, page 37. In these engines the gas and air supplies are both fitted with regulating-valves. These are shown below the horizontal cylindrical casing in Fig. 14, the gas-valve being that to the left, and the air that to the right hand. After these valves the gas and air pass into two separate compartments in the back head communicating with either end of the cylindrical casing. Inside, this casing is divided into three compartments by two vertical partitions. The left-hand partition has a hole in it, and forms the seat for a valve. The right-hand partition also has a circular hole in it. Through the casing runs a horizontal spindle, on which is fixed a valve closing the outlet from the gas compartment to the central of the three chambers. On this spindle is also a circular disc or baffle, which, however, does not completely close the hole in the other partition between the air and the central chambers. A movement of the valve-spindle to the left allows gas and air in proper proportions to enter the central or mixing-chamber. The amplitude of the mixing-valve movement, and, therefore, the quantity of the charge, is governed by the position of a distance-piece or sliding fulcrum between two levers. The first lever is operated by the cam-shaft, its motion being transmitted to the second through this sliding fulcrum, the level of which is controlled by an arm which is raised or lowered by the governor. If it is lowered, the movement is large; if it is raised, it is reduced, and a smaller charge is taken in. This engine and plant were running daily during the Show for ten hours in a manner which left nothing to be desired.

On the small four-cycle horizontal engines of Messrs. Petters, Limited, of Yeovil, to which we referred last week, which start on petrol and run on paraffin, governing is accomplished off the exhaust-valve with a hit-and-miss gear which cuts a charge out. In this gear there is a special exhaust lever, of which we give an illustration in Fig. 15. A cam-operated lever forming part of the exhaust lever has pivoted to it, at its outward end, a governing lever weighted at its upper end. The up-and-down movement produced by the cam tends to make the weight kick. This tendency is controlled by an adjustable spring, so that the governing action may be set for a certain range of speed. If the amplitude of the movement of the weighted end of the lever rises above the normal, owing to increase of speed, a striker and lip do not engage, and the exhaust remains closed, the products of combustion remaining in the cylinder. The half-compression gear is thrown in by shooting and locking a simple bolt, which can be equally quickly released, and is then returned to the normal position by a small spring. Magneto ignition is adopted. This is also employed on the firm's well-known pattern of small two-cycle engines working on paraffin.

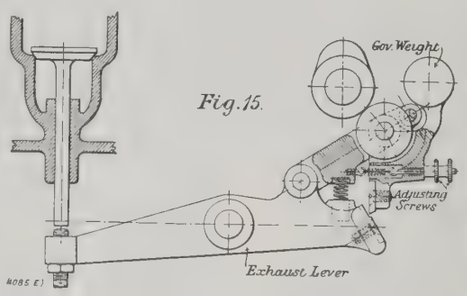

Fig. 15.

FIG. 15. GOVERNING-GEAR FOR PETTER OIL-ENGINE.

An interesting design of motor-plough was shown at the stand of the Wyles Motor-Ploughs, Limited, 2, Collingwood-street, Newcastle-on-Tyne. Two of these implements were on view, one fitted up as a plough and one with a cultivator attachment. The machine created a good deal of interest, being of such a size as to replace ordinary horse ploughing, and therefore coming within the reach of a fairly large number of farmers. We illustrate the plough, shown in Figs. 16 to 18, page 39, of which Figs. 16 and 17 show views of the machine but without the shares. The plough has a $4\frac{3}{4}$-in. by $6\frac{1}{4}$-in. single-cylinder, four-cycle internal-combustion engine of $8\frac{1}{2}$ brake horse-power, using petrol, benzol, paraffin, or alcohol. The engine and gear-box are arranged to form one unit placed at the front, and are carried upon frames of channel steel which extend the whole length of the machine. The main-drive clutch, of the cone type, is fitted within a pulley arranged to drive by belt all forms of farm machinery, *e.g.*, chaff-cutters, sheep-shearers, pumps, hay-elevators, root-pulpers, &c. By arranging the clutch within the pulley in this way, and carrying the pulley itself, by means of a sleeve, on ball-bearings, all stress set up by the belt pull is entirely removed from the engine bearing, and the belt-drive is operated through the clutch.

The drive to the road-wheels is by Renold roller-chain to the first-motion shaft, and then by cut-steel spur-wheels to the main driving shaft. Two speeds are provided by sliding pinions on the first-motion shaft. The whole of the gearing, including the chain, is entirely enclosed in an oil-tight and dust-proof gear-box provided with inspection doors. There are two one-way hardened-steel clutches on the main driving-shaft, so arranged that while both wheels are positively driven, either wheel is free to overrun the other for steering purposes, or either wheel may be driven alone. The controls for this purpose are in the form of hand-grips under the left plough-handle. The control for the friction-clutch is a similar hand-grip under the right handle. The engine is governed to run at a constant speed of 1000 revolutions per minute under all conditions, and the operator is free to give all his attention to the clutches.

In order to run with one wheel in the furrow and the other on the top of the land when ploughing, each wheel is mounted upon a radial arm capable of movement around the pinion, thus giving vertical movement while retaining the correct gear centres. The right-hand wheel is held in any desired position by means of the hand-wheel and screw adjustment shown. At the end of each furrow, in order to lift the ploughs to the surface of the ground, and to obviate any tilt of the machine while traversing the headland, it is necessary to bring the left-hand wheel into the same vertical position, relative to the frame, as that occupied by the right-hand wheel. This involves lifting the whole frame of the machine on the left-hand side, and to effect this easily and rapidly the following novel power arrangement has been introduced. It will be seen in Fig. 16 that a double set of ratchet teeth are provided on an extension of the radial arm carrying the left-hand road-wheel. With these ratchets two pawls, mounted upon the frame, or rather upon the gear-box, engage. These pawls are operated by a single lever, shown upon the handles of the plough, in such a manner that each pawl comes into operation as the other is removed. The action is as follows:—On releasing the upper pawl the frame falls by gravity to the position shown in the drawing. The exact depth of ploughing is set by the hand-wheel and screw adjustment. On reaching the end of the furrow the lever is thrown over, thus disengaging the upper pawl, and the pressure of the teeth of the driving pinion, engaging with the gear-ring on the road-wheel, is sufficient to raise the frame; that is to say, that the driving pinion, instead of causing the wheel to revolve, climbs up round the gear-ring, and so raises the frame. The movement of the lever in removing the upper pawl permits the lower one to fall into place and retain the frame in its elevated position.

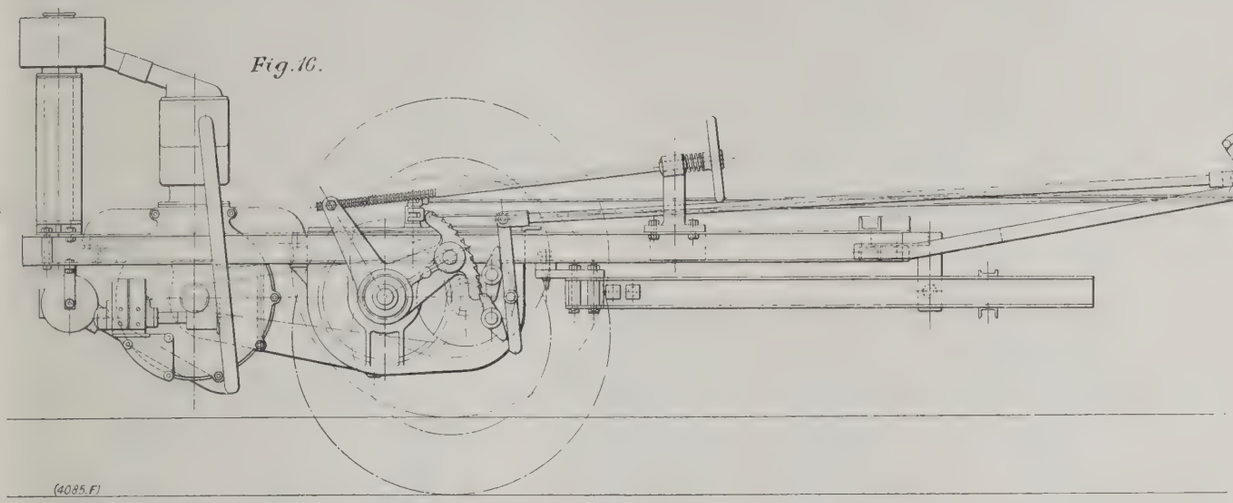
Thus the ploughs are lifted to the surface of the ground without stopping the machine, and then by driving one wheel only the plough is swung round upon the other wheel as a pivot. This form of lifting-gear has been evolved after long experiment. The simplicity of the arrangement now adopted is noteworthy, there being no gearing, either hand or power, in connection with the scheme, apart, of course, from the main driving gear.

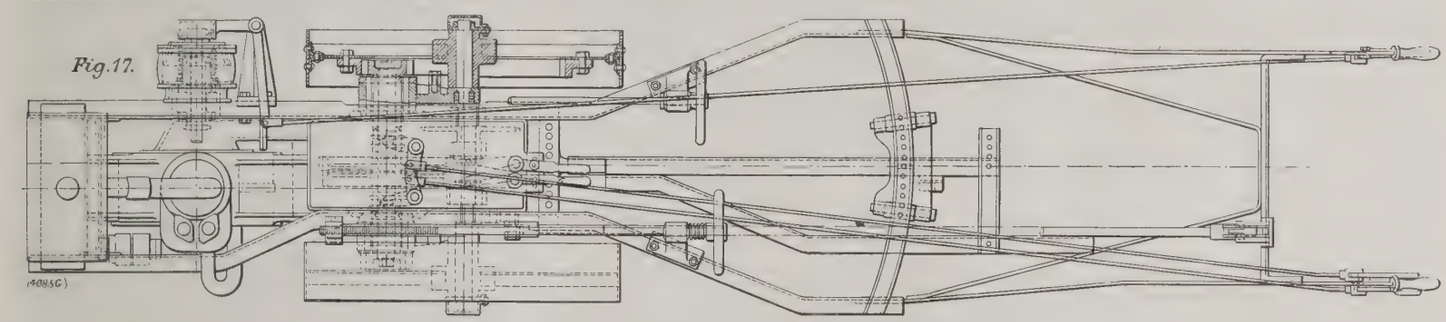
The maximum wheel adjustment allows for a 10 in. depth when ploughing one furrow. The machine is exceedingly well balanced and easy to manipulate. Traverse is arranged at the back end of the frame and plough-beam by means of a roller-frame. The work done is exactly of the character of that performed by horses. Three acres per day can be accomplished for a fuel consumption of about $1\frac{1}{2}$ gallons per acre. With labour at 4s. per day, and fuel at 1s. 3d. per gallon, the cost works out to between 3s. and 4s. per acre. The plough is arranged for turning two furrows. The shares are not shown in the drawing, owing to the variety in use. The plough can be removed for replacement by a cultivator merely by withdrawing the draw-pin. After the first furrow is cut the plough becomes self-steering, and has been worked unattended except for turning at the ends of the furrows. The length of the machine is 12 ft. over all, and its width over the axle-caps 2 ft. $4\frac{1}{2}$ in. Its weight, with the shares, is 12 cwt.

One of the most novel ploughing-machines exhibited was that by the Darby-Maskell Motor-Plough Syndicate, 49, North-road, Lancaster. This is a machine weighing 5 tons, and supported on three travelling wheels, the two leading being provided with motor-car steering, and the trailing-wheel having two wide treads; the four treads are out of track. All wheels are driven. The engine is a 40-brake-horse-power four-cylinder Maudslay petrol-engine, mounted on the frame at the leading end of the machine. The leading wheels are spring-mounted, and are both gear-driven from a transverse shaft, fitted inside the pinion on each side of the machine with universal-motion transmission. The back wheel is chain-driven. The machine carries behind a V-shaped frame, the V being horizontal, pointing out behind, with the wings reaching some distance up the length of the machine. Each wing is a frame carrying two large enclosed sprockets, round which work a long endless chain. The sprockets and chain-boxes, the latter providing roller-paths for the link-pins, are inclined slightly to the vertical, inwards at the bottom.

Each chain carries six plough-shares; each share is in two parts, attached to separate links, so that when on the horizontal they match properly, but will also pass round the end sprockets. There is a large vertical gear-box at the point of the V at the back of the machine. The endless chains are driven from this, its drive being from the main shaft, transmitted by a heavy Cardan shaft. The machine travels forward at from ½ to 1 mile per hour, and three ploughs are at work simultaneously on each side. The machine makes V-shaped furrows all down the field, each share starting to plough 9 in. in advance of the previous one. It therefore ploughs six furrows at the same time. The ploughing action assists the machine forward to some extent. The machine ploughs up its own wheel tracks. The whole plough-frame is suspended at both ends by chains passing over pulleys on a kind of crane rigging, so that both ends of the plough-frame are raised or lowered at once. The machine turns in little more than its own length, and can plough into corners. The V-shaped frame can be detached and the machine used as a tractor, or the plough-shares can quickly be changed for cultivating-tools, either tines or discs. The controls, steering, &c., are brought to the driver's platform. The machine has been constructed for the Darby-Maskell Syndicate by the Eagle Engineering Company, Limited, of Warwick.

At the stand of Messrs. Richard Garrett and Sons, Limited, Leiston, a variety of machines were shown, including a compound semi-portable, a 7-horse-power traction engine, steam motor-wagons, &c. The most novel exhibit was, however, the Garrett-Crawley agrimotor, for ploughing and other purposes. This machine has a long frame of rolled steel section, mounted on two main carrying-wheels, a land wheel trailing at the rear end. A 25 to 30 brake-horse-power four-cylinder petrol-engine is mounted at the leading end, with cone-clutch transmission to a longitudinal shaft. The drive to the main wheels is by worm off the longitudinal shaft to a transverse shaft, and thence to the wheels by chain and sprockets. There is levelling gear for the near main wheel, the trailing land-wheel also being adjustable as regards height. The machine, when fitted with a three-furrow plough, is very nicely balanced. Either of the main wheels can be de-clutched for turning, the drive being then only to one which will work the machine round. The plough is suspended at the front end by links under the main frame, and is pivoted at the back end. The front end can be raised by levers and rods from the end of the machine; the back end can be adjusted for different heights by putting the pivot in one or the other of a series of holes in the land-wheel frame. The beam of the plough can be swung over at the back end on a roller-path by a hand-lever for steering. The main wheels can be shifted out and in on their axles, so as to obtain some variation in gauge, to clear crops. The whole machine weighs only 30 cwt. in working order, and has a speed of 3 miles per hour. It will plough 5 acres a day at a cost of 4s. 6d., compared with 10s. for horse work. The plough is really self-steering after the first furrows are cut. It was recently sent from end to end of a field unattended, except for a man at each end of the furrow, to turn it round. All controls, except the levelling gear for the near wheel, are brought to the back end of the machine.





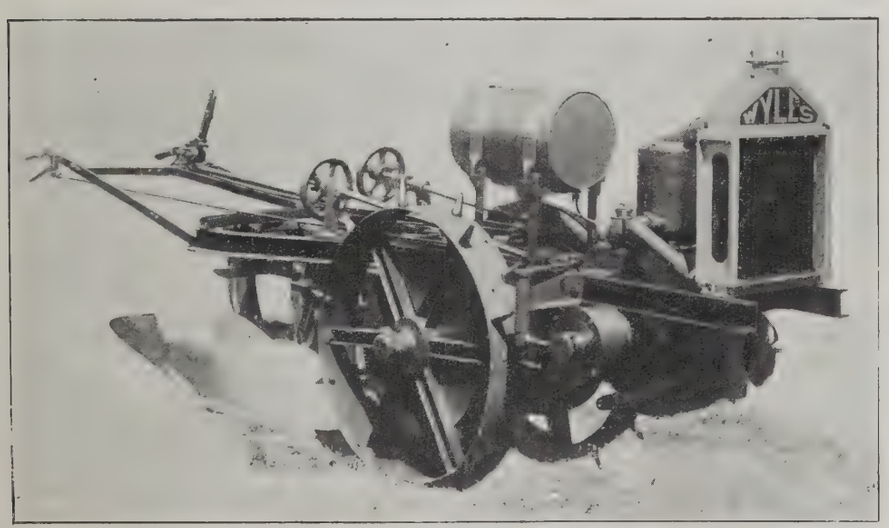


FIG. 18.

FIGS. 16 TO 18. WYLE'S 8½-HORSE-POWER MOTOR-PLOUGH.

At the stand of Messrs. H. R. Marsden, Limited, Leeds, a new machine was shown in the form of a portable self-propelling stone-breaking plant for road-making. This is known as the Blake-Marsden macadam plant, being constructed to the Taylor-Marsden patents. The plant consists of a four-wheeled steel-framed chassis, on which is mounted a 16-in. by 9-in. frictionless hammer-action stone-breaker with a Marsden elevator, overhead screen, loading hoppers, together with a 25-brake-horse-power oil-engine, gear-box, &c. The sides of the stone-breaker are of mild steel, and the ends of cast steel. The moving parts are balanced, and friction losses are reduced to a minimum, the power taken being only about 60 per cent. of that taken by the original Blake-Marsden eccentric machines. From the breaker the stone passes to a short revolving screen in two sections, which separate out the dust and small chippings, passing the large stone on to the elevator, in the buckets of which it is raised to the top of the machine. It is here passed into a revolving screen of two sections, one of which passes 1½-in. and the other 2¼-in. stones into separate hoppers, provided with doors high enough above the ground to permit of a cart being backed up underneath. The oil-engine is arranged

at the front end of the frame, and drives the back wheels by chains and sprockets. The gear-box will give two speeds—namely, 2 and 5 miles per hour, and a reverse. The stone-breaker is belt-driven. Steering is done by the front wheels on the ordinary traction-engine system.

Several interesting displays of weighing machinery were to be seen, the greatest novelty being, perhaps, an automatic weigher at the stand of Messrs. W. and T. Avery, Limited, Birmingham, for weighing liquids, and suitable for water, oils, liquid fuel, sugar-cane juice, &c. This machine consists essentially of an even-armed beam, with a weight-box at one end and a hopper at the other, the hopper balancing the empty weight-box. In the weight-box are placed weights to the load it is required to weigh off, which, according to the size of the machine, may be anything up to several tons. The weights in the box draw down that end of the beam, which action opens a gate-valve of the guillotine type over the hopper, and the liquid to be measured flows into the hopper. As soon as the weight of liquid balances that of the weight in the box, the beam tends to swing level, the gate-valve is closed, and the supply cut off. At the same time the hopper is designed so that it overbalances at this stage, empties, and then rights itself, the weights pulling back the beam to the original position when the valve is again opened for filling the hopper afresh. A cam-stop is provided to prevent the hopper tilting over if it should be desired to check by pointers the correctness of the balance of the load and weights.

A complete milling-plant of a capacity of 1 to 1½ sacks per hour was shown running at the stand of Messrs. Thomas Robinson and Son, Limited, Rochdale. This plant was entirely automatic, one attendant being in charge, but having practically nothing to do. It was driven by an oil-engine, the complete plant requiring only about 10 horse-power. This exhibit included a scourer, a cyclo-pneumatic separator, a three-pair high mill for first, second, and third breaking, two double reduction mills, a sextuple plansifter, and a centrifugal bran-dressing machine. The installation was fitted throughout with the necessary elevators, trunks, &c., and all the machines were totally enclosed. The bearings in most cases were of the ball type, self-lubricated throughout, and well clear of the interior parts of the machines. The whole exhibit, including the platform on which the machines were staged, occupied a space of 25 ft. by 20 ft. The plansifter was of the double-crank type, supported from the floor on legs, with ball and socket joints. At another part of their stand Messrs. Robinson had another plansifter on a similar principle at work, and also one suspended from overhead by cranes, the motion being obtained from an overhead belt brought down to two pulleys at the edge of the plansifter, and from thence round a pulley in the centre of the machine, which drove an unbalanced weight. The new cyclo-pneumatic separator was described and illustrated in ENGINEERING of the 26th ult., page 873, and need not be again referred to. The firm also showed double diagonal roller-mills with a new adjustment gear, so that both ends of the rolls may be adjusted by one movement. A model sack-chute on Messrs. Robinson's system was also an interesting little device. This sack-chute is arranged with circular arc slides between the floors, but instead of being continuous the direction of the arc is reversed at each floor. The sack may be said practically to wriggle down, and arrives at the bottom with very little greater speed than at the intermediate floors. Sacks can be run out on any floor, and the whole chute can be accommodated in a corner of the building.

The general finish of the metal and wood-work in Messrs. Robinson's machines must be, we should think, unsurpassed in excellence. It is a very noticeable feature of the firm's products.

We omitted to mention when dealing with Messrs. Ruston, Proctor and Co.'s exhibit last week that some of their machines are now fitted with ball-bearings. Our attention was directed to a 4-ft. 6-in. thrashing-machine and a clover-huller provided in this manner, which, we understand, are the first applications of ball-bearings to be made to machines of this character. The bearings are of very simple design, the balls running in a ring-cage, the shaft being turned and the plummer-block bored to the proper fit. An end cap is fastened over the block by two studs and nuts. Once filled with grease, these bearings will run for a season without attention.

Among the smaller things a very interesting, and to some extent astonishing, water-raising device was to be seen at the stand of Messrs. W. H. Willcox and Co., Limited, 32-38, Southwark-street. This appliance, aptly termed the "Marvelo," is virtually a chain pump with nothing but the loop of an endless chain depending into the well. To keep the chain in place a deep-rimmed pulley is slung in the loop of the chain lowered into the well. At the top end the chain is run over a pulley-wheel worked by gearing by a hand-crank. The top pulley is enclosed in a casing, with a delivery pipe leading away from the lower portion. The chain consists of a link-chain surrounded by a spiral, Fig. 19. For large capacities a multiple spiral chain of the type shown in Fig. 20 is used. The lower part dipping into the well catches up the water while the spiral is opened by the curvature of the pulley, and retains the bulk of it till the highest part is reached, when the centrifugal force, while the spiral is bent open at the top pulley, throws the water out into the

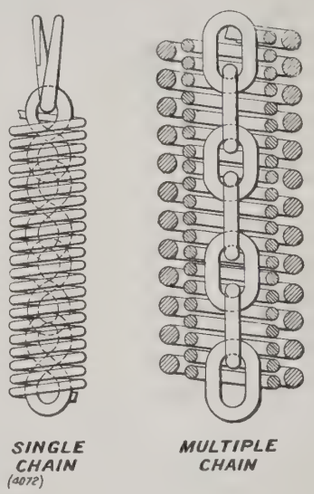

FIG. 19. FIG. 20.

FIGS. 19 AND 20. WILCOX'S WATER-ELEVATOR.

casing, whence it flows away. The capacity of this simple appliance is surprising, and it will handle water from depths of 200 ft. or more. The chain is made up in lengths of 3 ft. or 4 ft., which can be readily joined together to obtain the desired length. The apparatus requires no permanent fixtures in the well at all, and no buckets, guides, &c.

The Society held no trials of implements this year, though a number of new appliances were entered for the Silver Medal; many of these have been described above and in our previous article. In 1915 important trials are to be held in four classes. The first class will be devoted to direct-tractor internal-combustion plant of 20 brake horse-power or less, suitable for ploughing not more than four furrows 9 in. wide by 6 in. deep. A gold medal and 25*l.* will be awarded in this class. A similar award will be made in a second class for a direct internal-combustion plant of over 20 brake horse-power, or steam-ploughing outfit capable of ploughing not more than six furrows 10 in. wide by 8 in. deep. In another class, for which a similar award will be made, the self-propelled plough must turn not more than four furrows 9 in. wide by 6 in. deep; while in a fourth class a silver medal and 10*l.* will be awarded for a plough suitable for direct tractor work, and turning not more than six furrows. These trials will take place in August or September of next year, and final regulations will be issued in due course.

PORTLAND CEMENT.—A large new cement factory is about to be constructed in West Sweden, where extensive property has been secured for the purpose. The share capital is not to be less than 300,000*l.* and not to exceed 6,700,000*l.*

MERSEY DOCKS.—The Mersey Dock and Harbour Board proposes to erect, at a cost of 226,500*l.*, a shed 500 yards long by 50 yards wide on the south quay of the new Gladstone Dock at Liverpool, with the necessary cranes and railway lines for handling cargoes. The shed will occupy a space of 15 acres; it is to be a three storey building, and it is to be set back from the quay so as to allow space for a double set of railway lines. A final decision has not yet been arrived at upon the general subject.

THE INSTITUTION OF MECHANICAL ENGINEERS.

THE summer meeting of the Institution of Mechanical Engineers commenced at 9.30 A.M. on Tuesday last, the 7th inst., when members assembled in the hall of the Société des Ingénieurs Civils, 19, Rue Blanche, Paris. In the unavoidable absence of Sir Frederick Donaldson, owing to the strike at Woolwich Arsenal, the duties of chairman devolved upon Mr. Michael Longridge, Vice-President. The members of the Institution of Mechanical Engineers were first welcomed to Paris by Mr. Henry Gall, the President of the Société des Ingénieurs Civils de France.

In opening the proceedings, Mr. Henry Gall, speaking on behalf of the Société des Ingénieurs Civils de France, said that the agreeable duty which had devolved upon him of welcoming the Institution in Paris, was one which he undertook with the greatest pleasure, and added that he was glad at being accompanied on that occasion by one of their Past-Presidents, Mr. Gustave Eiffel, who had been made Honorary Life Member of the Institution of Mechanical Engineers. He was sorry Sir H. Frederick Donaldson was unable to be present at the Paris meetings, and he asked Mr. Michael Longridge to kindly convey to him the regrets of the Paris Société. He thanked the Institution for having selected their building for the holding of their meetings, and expressed the hope that the visitors' stay in Paris would be a pleasing one; he felt sure its effect would be to tighten the bonds of sympathy which united the two nations.

Mr. Michael Longridge, who, as we have stated, occupied the chair in the absence of Sir H. Frederick Donaldson, speaking in French, thanked their French colleagues for their most cordial reception, and for having put at their disposal their Paris building for the reading and discussion of the papers which had been prepared for the occasion, six of which, out of seven, had been written by French engineers. The President of the Institution was deeply sorry at having been prevented at the last moment from coming; he had been kept back by his duty to his country, and he (the speaker) would not fail to transmit to him the regrets which had been expressed by their excellent friend, Mr. Gall. The Institution had visited Paris the last time twenty-five years ago, and the members present who had taken part in that visit had retained the most pleasant recollections of it; he felt sure they would take away with them better recollections still of their present visit. He thanked the French Société for the trouble they had taken for providing both for their instruction and their enjoyment. He also thanked, in this connection, Mr. William Hanning, the President of the British Chamber of Commerce in Paris, and their own secretary, Mr. Worthington; such meetings involved a vast amount of trouble and work, and both these gentlemen had been indefatigable in their efforts. Speaking in English, he added that the absence of Sir Frederick Donaldson would prove a great disappointment, but he was not absent through his own fault, but through what their French friends would call a case of *force majeure*. On his motion, their French colleagues were accorded a hearty vote of thanks for all the kindness which had been shown to the Institution.

The Secretary next read the minutes of the former meeting, and then the names of the members transferred and newly elected. This terminated the ordinary proceedings.

FRENCH EXPRESS LOCOMOTIVES.

At the conclusion of the formal business the Chairman called upon Professor Ed. Sauvage to read his paper entitled "Recent Developments of Express Locomotives in France." This is reproduced *in extenso* elsewhere in this issue. Professor Sauvage summarised it, after which, before calling upon the meeting to pass a vote of thanks to the author, Mr. Longridge remarked that he could recall the time when the express trains on the Northern Railway of France were drawn by Crampton locomotives with large single driving-wheels at the back of the fire-box. These engines had necessarily very little adhesion. Their main advantages were supposed to be the low centre of gravity and the absence of coupling-rods. They had learned since then that coupling-rods were not such an evil as was once imagined, while a low centre of gravity was not so desirable as it once appeared. The main points of the paper related to

the advantages of compounding and superheating not taken by themselves, but in relation to the traffic to be handled, and to the question of the boilers of these enormous engines, which he thought rather valuable features. He hoped these points would be well discussed.

Mr. Henry Fowler, who was the first speaker, remarked that there was little to say, unless he entered upon the wide field of details. There were no passenger locomotives being built now in England without superheaters. Although the author had not gone into details, there was one matter he thought he might mention. It related to the tightness of the large smoke-tubes in superheater engines. When these tubes were of the ordinary length in English practice they did not have much trouble. When they were long—as, for instance, 16 ft.—the trouble of keeping them tight became serious. In a particular case he had in mind, the trouble, perhaps, arose on account of the exceptionally bad water; but if leakage once started, it was very difficult to stop. The author's remarks about dispensing with the smoke-box damper and gear in superheater engines were interesting. The same thing had been tried in England with success. It would be a good thing to get rid of this damper if possible. In England not much had been done in combining compounding and superheating; only two roads were doing anything of the kind. He thought the engine of the future would be the four-cylinder superheater compound. With regard to the pressure drop of 42½ lb. per sq. in., mentioned in the paper as occurring on the P.L.M. system, such a drop was against his experience. He had found that the drop due to the tortuous character of the steam passages was usually made up by the increased fluidity of the steam in a superheated state. On the Pennsylvania Railroad they had just produced a very large "Atlantic"-type locomotive, and Mr. A. W. Gibbs, of that system, considered that there was still a large future before this class of engine (4-4-2). With reference to Mr. Longridge's remarks on coupling-rods, he would say that no engine ran so well as a single-wheeler, and no engine slipped so readily when called upon to haul a load.

Mr. A. Herdner, Chief Engineer of the Southern of France Railway, who followed, said he regretted he was not really fluent in English, and asked to be allowed to speak in French. In the author's Table IX. there was a misprint. He (the author) had mentioned two-cylinder superheater "Pacific" locomotives; all the "Pacific" locomotives were now four-cylinder engines. The author had mentioned the coal consumption as being 14.1 kg. per km. in the case of the engines using superheated steam, and 14.616 kg. in the case of those using saturated steam; the difference was about 0.5 kg. per km., and that on a service of from 9 to 10 months. In the commencement the difference had not varied much, but it had decreased later. On locomotives provided with superheaters, it occurred that the cleaning of the superheater was liable to be neglected occasionally; the exhaust side was also liable to be neglected. The difference in coal consumption, however, had never exceeded 1 kg. per km., a result which he attributed to the too small size of the superheater; the latter might, perhaps, have a sufficiently large superheating surface, but then the section available for the passage of the hot gases was too small compared with the total passage section. In their present engines only 38 per cent. of the gases passed through the superheaters, and when they repaired these engines, they would increase the number of superheater tubes. The divergence that might exist between the locomotives of the Southern of France and the other French railways was more apparent than real. On the Southern of France they had many compound engines; they found that the construction of locomotives having four cylinders, but not compounded, was not justified, and he (the speaker) had always been of Mr. Sauveur's opinion in this respect. When using compounding and superheat, the number of cylinders to be adopted had to be taken into consideration, and when comparing together engines that were comparable, it was found that the steam consumption with two cylinders was much less than with four. The gain corresponded to a saving of about 1 kg. of coal on, say, 12 kg. to 13 kg. per km., which could only be traced to the difference in the number of cylinders, the engines being otherwise comparable one with the other. In this connection he gave the following figures for coal consumption:—13 kg. for a four-cylinder "Atlantic" engine using saturated steam; 12 kg. for a four-cylinder "Atlantic" engine using superheated steam; and for the two-cylinder engine about 800 grammes less (12.200 kg.) than the first. In these three instances the engines could be compared the one with the other. But he did not conclude therefrom that the two-cylinder engine using superheated steam should displace the four-cylinder one completely, for there were far too many variables to make it possible to draw a final conclusion. But if, for instance, upkeep were considered, the cost of upkeep of a four-cylinder engine was much higher than that of a two-cylinder engine. Further, the repairs to a boiler having a registered pressure of 15 kg. to 16 kg. per sq. cm. was more costly than those to a boiler for a pressure of 12 kg. to 13 kg. with superheat. He was now building engines of the "Pacific" type, having two cylinders, generally similar to the four-cylinder ones, with the same grate area and the same superheat, and was going to test them in comparison with the latter. He believed they would prove more economical.

Mr. G. W. Hutchinson was the next speaker. He referred to the experiments made on the Northern Railway of France with water-tube fire-boxes, drawing attention to the engine shown in Fig. 10 of the paper, which he believed was fitted with a water-tube fire-box. It would, he thought, be interesting to know how this design behaved in practice. Did the arrangement make for better steaming? Did the tubes require much attention to prevent leakage or frequent renewal? One way in which to increase the power of the modern locomotive was to raise the pressure. He did not know whether the ordinary fire-box would stand much increase of this kind, but he thought the water-tube fire-box offered a good chance of accomplishing this. If the water-tube box for high pressures were used with the ordinary barrel, the latter would have to be made extra strong, and would therefore become a good deal heavier. That would be objectionable from some points of view. He therefore thought a complete water-tube boiler should be devised. Possibly early attempts would prove failures, but success would doubtless come in the end. At previous meetings a common fund for experimental work had been suggested. He thought the production of a water-tube boiler a suitable subject for some such joint effort.

Mr. E. Ronceray said that he had not been connected with locomotive work for many years, but when he had been in former days he had always been under the impression that compounding had been adopted because the valve-gear in use was unsuited to high pressures. There were other gears now available, and he had himself recently designed a gear with constant lead, exhaust, and compression, the only variable being the cut-off. If a gear of that type had been adopted, he thought the compound would have made less headway. On Mr. Longridge requesting Mr. Ronceray to submit a drawing of this gear for inclusion in his remarks, he promised to do so.

In reply to the discussion, Professor Ed. Sauvage said that there was little really for him to comment on. With regard to Mr. Fowler's remarks on the drop of pressure on the P.L.M., the Northern Railway had had similar experience. Large ports and straight passages were undoubtedly necessary. French engineers would like to be able to use the 4-4-2-type engine instead of a six-coupled type, and they would do so to a much greater extent if the axle-loads permitted on the Pennsylvania Railroad were permissible on their systems. With regard to Mr. Herdner's contribution, the two-cylinder engines he spoke of would certainly be watched with interest. Of the "Baltic" engines referred to by Mr. Hutchinson only two had been built. They were powerful but expensive. The Northern Railway was very reserved as to their performances, &c. One of the two had an ordinary box, and the other a water-tube fire-box. The latter was not a success, and was in continual need of repairs. Though several companies in France had tried it, so far this type of box had not proved satisfactory. Mr. Ronceray's gear sounded interesting, and he hoped he would meet with greater success with regard to it than had some of the others that had been tried. The tightness of the large tubes did not present any great trouble; perhaps it would be interesting if he added to his paper details of the methods adopted to ensure this.

Compound Articulated Locomotives.

The next paper to be taken was one by Mr. Anatole Mallet, and was entitled "Compound Articulated Locomotives." This paper, which we reproduce elsewhere in this issue, was summarised in French by M. Mallet, who explained the principal features of his system by means of a model.

Mr. Longridge said the subject was one of special interest to those who had to do with pioneer railways where curves were sharp and grades heavy. In his locomotive days, the Fairlie engine used to be employed with success; the Fairlie was practically two locomotives coupled together. The joints of the steam-pipes used to give trouble then. He had once designed an articulated locomotive for heavy goods traffic; he had coupled his wheels by means of steel cogs. His attention had first been drawn to the matter by the work on the Mont Cenis route, where the grades were 1 in 8 and there were curves of 40 metres radius. The longest rigid wheel-base he believed had been then 8 ft. 6 in., and that had suggested the use of articulation. However, it was found that the two-cylinder type of locomotive, without any complication, was best after all. He would like to hear the later experience of others.

Mr. Edgar Worthington was called upon by the Chairman, and remarked that it was the first time since he had occupied the position of Secretary that he had been asked to contribute remarks to a discussion. Engineers owed a great deal to Mr. Mallet's work in the development of the modern locomotive, not only with regard to the articulated type, but also for his pioneer work in connection with double expansion. He (the speaker) had had twenty-three years' experience as a locomotive constructor. In the early days (about 1875-80) everyone looked to Mr. Mallet and his work to see if it was worth while spending money on developing compounding. At Crewe, under Mr. Webb, he had fitted the first Mallet arrangement used in England to an old Trevithick engine. Webb, Worsdell, and von Borries all followed Mr. Mallet in Europe. For a long while there was no development of that kind in America, but in India Mr. Sandiford took the subject up. That, perhaps, was wandering slightly from the subject of the paper. Fairlie engines had been worked on the Festiniog Railway before Mr. Mallet introduced his engine. On the previous visit of the Institution to Paris there had been Mallet engines at work on the Decauville railway. In the early days there had been trouble with the steam-pipe joints; that had now been overcome, but in the course of time many expedients had been resorted to with a view to finding a substitute for the Mallet engine. Some of them were expensive, as, for instance, the type of twin-engines adopted for the Kojak Tunnel in India. In this case there were two engines with one large tender between them, but ultimately more tenders were built, and the engines paired off with them. Mr. Mallet had come out at the top of all these experiments, as was proved by the wide-spread adoption of his engine in the United States.

Dr. H. S. Hele-Shaw said that he was not a locomotive man, but it might interest the meeting to know that there was in course of successful development an articulated system in which oil under pressure was conveyed from the locomotive to the driving wheels. The oil-transmission system was making rapid progress owing to the progress of the Diesel system, and by it flexibility, similar to that obtainable only with the steam-engine, would soon be a characteristic of the Diesel locomotive. The need of that flexibility was recognised. The articulation system to which he referred gave no trouble; the transmission of the oil through the joint at high pressure had been quite successful. This problem had given a good deal of trouble in connection with two rail-cars, but it had been overcome. He thought the transmission of steam through an articulated joint rather more difficult probably than that of oil, which acted as a lubricant.

Mr. F. H. Livens said he was not competent to discuss the paper from the locomotive man's point of view, but he would like information with regard to firing. With the increase in power and size of locomotives the boiler and grate were much enlarged. The difficulty of firing wide grates had been mentioned in Mr. Sauvage's paper, and preference had been expressed for narrow grates. Mr. Mallet's paper spoke of grates of 70 sq. ft. to 100 sq. ft. area. If there was difficulty in firing the grates

mentioned by Mr. Sauvage, what would it be in the case of these large American engines. He would like more information on the fire-box question. How many doors were there, and how much coal was fired? He thought great difficulties arose at the heat-producing end of the locomotive.

Mr. G. W. Green said he had just returned from Chili, where on the Nitrate Railways they used Fairlie engines. The lines were full of curves and heavy grades of 3 per cent. The best engines on that system were the Fairlies, some of which had been in use since 1864, the latest having been built in the shops in South America in 1911. There were no Mallet engines. The others were all fixed wheel-base engines, six-coupled. Their chief trouble was the coal, which had to be used either in the form of briquettes, or was so small that it had to be carried in sacks. He had not heard of trouble with the articulated joints of the steam-pipes. Some time ago they had had a Shey engine from North America. It pulled its load up hill all right, but when it was loaded with about 12 cars of 30 tons capacity each, and the train was run down the line at the usual speed, the gearing on the locomotive caused it to skid practically the whole way down, and it was not used again. The line rose about 3000 ft. in 25 miles.

Signalling on Trains in Motion.

The third paper to be taken on Tuesday morning was a composite contribution by the engineers of six different French railway systems. It was entitled "Signalling on Railway Trains in Motion," and described systems in use on the Northern, Eastern, Southern, State, P.L.M. and Orleans Railways. It will be reproduced in a future issue of ENGINEERING. In the meantime it is only possible to say that the system adopted on the Northern Railway was described by Mr. A. Sartiaux; that of the Eastern Railway by Mr. F. Lancrenon; that of the Southern by Mr. A. Herdner; that of the State Railways by Mr. A. Claveille; that of the P.L.M. by Mr. L. Maréchal; and that of the Orleans Railway by Mr. E. Solacroup. In many cases the authors themselves were unavoidably prevented from being present, but in most instances a short verbal description of the apparatus was given, either in French or English, by some one connected with the railway in question. The systems referred to embraced audible or visible cab signals with rams or "crocodiles" in the road, usually in between the rails.

The first speaker on this subject was Mr. J. A. F. Aspinall, Past-President, who said that as that was the first paper to be read on the subject, it might be supposed that the subject had not received much attention in England. That, however, was not the case. They had, on the North-Eastern Railway, the system developed by Mr. Raven, and on the Great Western Railway there was another of a somewhat different type. In France the subject had received attention for a long time. In 1875 he had come over to see the system developed by Mr. Lartigue on the Nord, which was still in use in a modified form. He also greatly appreciated the courtesy which had enabled his colleagues recently to see what was now being done in France. In England we had been slow to adopt such systems, because we preferred to rely on the thoroughly-trained enginemen and signalmen. The systems described transferred the responsibility for everything being in order from these well-trained men, who appreciated their responsibility, to a body of electricians who had to attend to the condition of the contacts and connections, not only all over the system, but also on all the engines. These electricians, who, after all, were of the nature of ordinary wiremen, had not nearly the same sense of responsibility as the drivers and signalmen. That, perhaps, might be answered by reference to the fact that the machine itself reported, so to speak, whether it was in order or not. That was so in some systems, but not in all, especially in the simpler type, which, however, offered some advantages. Imagine the thousands of men coming into business in our great cities of a morning held up because some little contact had failed. It was not a question of cost, or of dislike, but much more so of the uncertainty with regard to the reliability of the present-day systems which prevented their wider adoption. Referring to another matter, it became necessary a few years ago for every gang of platelayers to be provided with a watcher. The responsibility was withdrawn from the men themselves and transferred from, say, six pairs to one pair of eyes. Accidents to these men had greatly increased as a result, and if the watcher was abolished he thought the accidents would certainly decrease. If we adopted apparatus of this kind, he thought the miniature signal in the cab inadvisable. The sounding apparatus was better, because it was unwise for the driver to take his attention off the road. The audible signal was effective in attracting his attention. With all these systems a brush contact and a ramp or crocodile were used. The most convenient places for these were naturally in the centre of the engine and track. But now that electrification was being adopted, and a fourth rail was employed, it was impossible to put the ramp in the centre of the track; also there were water-troughs in the centre of the road. If the brush were put low, it would clear the water out of the trough; if high, it would not touch the ramp; while if the ramp were placed high, it might foul the water-scoops. It therefore became necessary to put the ramp to one side. That involved the use of two brushes. They were experimenting on the Lancashire and Yorkshire Railway in the directions he had mentioned, and sincerely hoped that they would arrive at satisfactory results.

Mr. H. Fowler said that on the Midland Railway they had a branch fitted up with the Great Western system. He thought the length of the "crocodiles" used on the French railways was too short. In England the flat length adopted was about 20 ft. He thought they had been slow, because they had foreseen the difficulties which the system introduced. One of the gears described adopted a spring in the whistle gear, on which the whistle action was dependent. They had tried to keep clear of all parts like that which might be liable to derangement. He would be glad to hear whether any difficulty had arisen from the spring breaking. There was nothing to show "line clear" on the French systems, as far as he could see. That, they considered a necessary indication in England. He would also like to know whether any difficulty arose with the tripping lever shown in Fig. 18 of the paper, and whether it was liable to damage on being struck at high speed. Such levers were not regarded with favour generally, and such parts were often, he thought, liable to harm from almost inexplicable causes, stones lifted from the ballast, and so on.

Mr. W. A. Stanier spoke of the Great Western Railway system, known as the audible cab system, using a T-shaped ramp placed centrally in the 4-ft. way. The engine carried a contact and had a battery circuit. In a box in the cab was an electric bell and a siren. In the event of a failure the siren sounded. Ramps were at present fixed at the distant signals, and on two branches the line had been converted to this system at the distant signals. On single lines polarised relays energising the ramps prevented the engine getting a wrong indication. The recent improvement had been the application of the system to the control of the brake, and a train could be pulled up even with the regulator full on. The driver could not blow off without attending to the signal. The drivers were getting used to the system, but at first they seemed to prefer to see something. On the main lines the general opinion was that it was all very nice, but they could not see the action of the signals ahead, and it seemed to lead to delay. In fog, however, it worked otherwise. Men with the system on their engine worked to time. As a result, the system was likely to be extended. Mr. Aspinall's requirements he considered to be filled by the Great Western system. The point raised about the wiremen and electrical contacts was covered by ensuring a danger signal being given in case of failure. No small semaphore was used, but an audible signal. The ramp was fitted in the centre of the track and was of reasonable length.

Mr. P. M. Baker said that his experience in India led him to make a reference to Mr. Aspinall's remarks on first-class men, which, of course, did not apply to that country. Twice he had lately been stopped in the most important train crossing that continent on account of both the station-master and signalman being away from their posts. Several times drivers waiting by the roadside had heard signals go off, and had jumped on their engines and started without troubling to see whether they were for them or some other train. Anything which would prove reliable, and would repeat the road-signals and apply the brake, would be an advantage. As far as he could see, the systems described provided no means of detecting broken circuits, except in one case. A danger signal which failed was worse than no signal at all. The Great Western system gave a danger signal in the event of any failure. Then there was the probability of failure of the contact. How were the brushes made reliable? He would be afraid of getting shorts on the wiring to them. The Krammer-Kapp system of induction, he thought, had advantages over these contact systems. In this system two balanced inductive circuits were used, and it went to "danger" if anything failed with one circuit. Its chief disadvantage was the need of a motor-generator or some other means of providing power. He would like to know the percentage of failures to movements in France on the systems described.

Mr. Moutier, who had introduced the subject, speaking on behalf of his company, the Northern of France Railway Company, said, in reply to the discussion, that all the remarks which had been put forward by Mr. Aspinall were important, and would be gone into by them with all due attention. The question, however, resolved itself purely and simply into a question of principle; it was purely and simply a matter of deciding whether the repetition of signals upon the engine foot-plate formed an integral factor of safety, or merely an additional guarantee. If it were considered as forming part and parcel of the railway signalling system, it was dangerous, and it would be better not to have resort to it. It was useless to add to the usual signalling apparatus, which worked satisfactorily, another—a new device—which would only act as a kind of brake on the former, and complicate matters; the new device would have to be absolutely impeccable. If, on the other hand, the new device be simply considered as an additional, an invisible extra guarantee, when it failed, the driver would remain, and would act in his full capacity, no accident occurring should the additional guarantee fail. It was necessary, therefore, to consider the device simply in the light of an aid; where this had been done in the correct light no inconvenience has resulted. The light in which it is considered was probably the only point which divided the engineers of the two countries. He advocated, therefore, the use of the device simply as an addition made to the present existing means of safety. In regard to the recording by the device both of an open line and a closed line, there were two schools of thought.

Some engineers had stated that the device led the engineer to consider solely what occurred on the footplate, and he lost the habit of watching the signals on the track. From this there was but one step to proclaim that the latter signals would become useless. But if these were done away with, the publicity they afforded would also be done away with; it would be impossible to ascertain where a driver had failed. When it was said that the apparatus led to accidents, all depended upon the point of view from which the question was considered. If the device were considered as an adjuvant, a kind of mentor, all difficulty was brushed away.

Some speakers found the fixed ramp, or "crocodile," too short; but it could be made longer, and if longer, the number of misses would be less. Were it never frosted over they would be less still. The ramp was a "mentor," and when it did not work, the "mentor" was simply absent for the time being. It could be lengthened and thereby reduce the number of times it failed to act. Mr. Briard, for the Eastern of France Railway, had explained his device in which the ramp contained petroleum, thereby obviating the difficulty due to frost and rust.

In regard to the regulation of the spring for the whistle signal, that part of the device entered into the whole simply on the lines he had indicated, those of an additional guarantee. The life of the contact brush had also been mentioned, but this was not a costly element; the brush was easily supervised and easily replaced when worn.

Referring again to Mr. Aspinall's remarks, he (Mr. Moutier) said that on the Northern of France they had no electric traction. But this was a consideration for both the Paris-Orléans and the Southern of France Railways. Mr. Aspinall feared that the brush might be too high and miss contact, or too low, when it would be liable to tear up the "crocodile." The cases in which it would be too high were very few, and if too low it could not tear up the "crocodile," since a wooden shield on a slope was in front of the "crocodile,"

up which the brush travelled before it arrived on the latter. He, however, had noted Mr. Aspinall's remarks in regard to the stray currents that might occur on electrified lines. He thought he had replied to all the remarks, and emphasised the fact that the device should simply be viewed in the light of a vigilant mentor who, should the driver become inattentive, would "tap him on the shoulder, calling him back to his duty."

On the motion of the Chairman, the authors were awarded a hearty vote of thanks for their contribution.

On Tuesday afternoon various alternative visits had been arranged, as, for instance, to the works of Messrs. A. Darracq et Cie., the Établissements Baudet et Donon, the Compagnie Electro-Mecanique, or the Conservatoire des Arts et Métiers. In the evening the Institution Dinner was held at the Hotel Continental.

PROCEEDINGS OF WEDNESDAY, THE 8TH INST., &c

On Wednesday, the 8th inst., members reassembled at 9.30 A.M. for the reading and discussion of papers. Four papers were considered—viz. :—"The New Niclausse High-Duty Marine-Type Boiler," by Mr. J. Niclausse; "Development of Internal-Combustion Engines for Marine Purposes," by Mr. Drosne; "Balancing of Internal-Combustion Engines," by Mr. H. F. Fullagar; "Improvements in Motor-Lorries," by Mr. E. Brillié. These we shall reprint in an early issue, and the discussions will be dealt with in our next issue. In the afternoon of Wednesday visits were paid to the works of Messrs. Niclausse; of Messrs. Hotchkiss and Co.; of the Société Anonyme des Etablissements Delaunay Belleville; of the Société Général de Constructions Mécaniques; and to the Fonderies et Ateliers de la Courneuve. In the evening a conversazione was held at the Société des Ingénieurs Civils, by the invitation of Mr. Henry Gall, Mrs. Gall, and Members of Council of the Société. On Thursday and to-day other excursions have been arranged, including, to-day, visits to works at Le Havre, Valenciennes, Lille, &c.

(To be continued.)

INDUSTRIAL NOTES.

AT a labour conference held on Wednesday at the Caxton Hall, Westminster, a scheme for consolidating the whole of the bodies affiliated to the National Transport Workers' Federation and the General Labourers' National Council into one consolidated union, with an estimated membership of 400,000, was approved. In addition to the thirty societies represented at the conference by 150 delegates, several of the smaller unions had expressed approval of the amalgamation. According to a statement made after the conference by Mr. Robert Williams, secretary of the Transport Workers' Federation, twenty-six societies expressed entire approval, two were against it as drafted, and two remained neutral.

During the past and present weeks there has been a very serious strike at Woolwich Arsenal. It commenced last Friday, the 3rd inst., in consequence of an employee refusing to erect a machine upon a concrete foundation which had been laid down by non-union labour during a strike. The man was brought before the Chief Superintendent, Sir Frederick Donaldson, and, upon persisting in his refusal, was discharged. Thereupon there was a general strike in the Royal Carriage Department, some 1500 men of the Amalgamated Society of Engineers coming out. On Saturday many other men followed their example, until there were between 7000 and 8000 out. The Labour Protection League announced that all the labour organisations had ordered their men to come out solidly and every gate at the Arsenal to be picketed. On Monday only a few hundred men, out of some 11,000, remained at their posts in the Royal Laboratory, Royal Carriage Department, Royal Gun Factory, Mechanical Engineering Department, the Building Works Department, and in the Army and Navy Ordnance Department. There was also a suggestion of calling out all the workmen at the Government dockyards at Plymouth, Devonport, and Portsmouth. The more important unions involved were the Amalgamated Society of Engineers, the Labour Protection League, the Workers' Union, the Coach-Builders, Steam-Engine Makers, Associated Smiths, Wheelwrights, Electrical Workers, and Ironfounders. On Tuesday the local Labour leaders and Mr. Will Crooks, M.P. for Woolwich, had an interview with Mr. Asquith, and later in the day the Prime Minister stated in the House of Commons that the Government had decided to appoint a Court of Inquiry, consisting of five persons, with Sir George Askwith as chairman, to inquire into and report upon the origin and circumstances of the dispute. The strike committee met on Tuesday night, and after a further discussion with Sir H. F. Donaldson, it was announced that the following terms had been agreed upon :—

(1) All men to return to work in their former position. (2) The Court of Inquiry to deal with the principle which has led to the dispute. (3) Whatever the result of the inquiry, whether in favour of the men's contention or not, Entwistle, who originated the dispute, and any other man similarly placed, not to be punished. (4) Where building work has already been executed, the men to be recommended to offer no objection to working upon it, provided their work is followed by no "black-leg" labour.

This is an opportunist settlement which settles nothing, and leaves the matter to be fought out at some future date.

The Insurance Commissioners recently issued the draft of a Special Order which deals with the insurance of casual labourers in the Port of London, and is intended to meet two difficulties. Casual men in the Port of London are very generally employed by the day or half-day. Under the ordinary provisions of the Insurance Act the first employer was liable for the whole contribution, and after Monday there was, therefore, a tendency in selecting men to give preference to those whose cards had already been stamped. One consequence of this state of matters was that men who did not obtain work early in the week were induced to stamp their own cards. This, of course, meant a heavy burden on the casual men, a considerable proportion of whom could not rely upon more than two or three days work in the week.

It is now proposed that all casual men employed in the Port of London, between Westminster and Gravesend, in loading or unloading ships or craft, or in warehousing goods, will be required to deposit their insurance card at one of the special offices or clearing-houses to be established by the Commissioners, and they will receive in exchange a numbered tally, which will act as a means of identification.

Every employer will be required to make a return once a week of the tally numbers of the men he has employed on each day of the week. He will also be required to give to each man he employs a voucher for each day of employment.

When giving evidence before the Royal Commission on Railways, on Thursday, the 25th ult., Sir Charles Owens, director and late general manager of the London and South-Western Railway Company, stated that his objections to nationalisation related to political pressure, the enormous character of the undertaking, the absence of elasticity in fixing experimental rates, and the lack of efficiency under Government departments. His experience of Government departments was not such as to induce him to expect the same average of efficiency as was obtained under the administration by commercial men.

To the remark that under unification the railways could be worked by a central administration in the district, and divisional officials, as under the present system, Sir Charles agreed, but he added that a unified system with central administration would be an enormous undertaking, and would have to be worked more or less on the Post Office system, and he did not think it would be satisfactory. The tendency of amalgamation and absorption had been in the first instance for the larger companies first to lease and work the smaller concerns. But under complete unification the idea would be to place all railways under one management, and he did not think Parliament would be inclined to hand over the railways to any such central body. He was aware that in America railway companies controlled very much larger areas of distance than in this country. But the class of work considerably differed. In America it was a wholesale business, but in England the work was of a much more general and retail character. For this country he could conceive no better system than the existing amalgamations and working agreements, and he did not think he could recommend much larger units.

In regard to the grouping of companies in zones or divisions, and for the railways operating in those zones to be constituted in one company, he said that such an end would be desirable, but he thought it would be more likely to be attained by removing restrictions which were sought to be placed on companies, and by removing difficulties in the way of getting further powers, than by legislation in the way suggested. If he might be allowed to say so without offence, the policy of Parliament had been constantly to facilitate the inclusion of one railway company in the district of another.

He was in favour of railways being grouped into zones and placed under the management of one company in the interests of shareholders, traders, and the public generally. The public were already getting large advantages by this system of combination.

The general manager of the London and North-Western Railway has recently announced that important concessions will be made to the members of the company's staff. A regrading affecting 1700 persons on the system is to take effect on August 1, the details of which will shortly be issued. There is to be a general promotion to higher classes, involving increases of 10*l*., 20*l*., and 30*l*. yearly, and all receiving the 90*l*. maximum (the lowest class) will now receive 100*l*. The rise will affect the superintendents and the clerks at the passengers and goods stations; it has been brought about by the fact that, with the growth of the company's business, work and responsibility have increased. The concessions, it has been stated, will cost the company thousands of pounds a year, and the cost will continue increasing, since the rise in salaries is permanent, and affects every class of clerk.

The Scottish District Minimum Wage Board have issued an award in regard to the application of the Scottish miners, referred to on page 875 of our last volume, for an increase in the minimum wage from 5s. 10d. to 7s. 6d. per shift, and by other grades of underground workers to a corresponding extent. It has been decided to bring the wages of firemen and shot-firers, who act as firemen, from 5s. 6d. to 5s. 10d., the change to take effect from the first pay-day after the date of the award. No change is made in regard to the other grades of workmen.

At the meeting of the Leeds City Council, held on the 1st inst., a scheme for establishing a thrift fund for the employees of the Leeds Corporation was entered into. It is proposed that the employees shall contribute to the fund at the rate of 9d. in the pound on their wages or salary, the Corporation contributing a similar amount. Compound interest is to be paid at the rate of 3¾ per cent. per annum, and the accumulated sums are to be available on retiring at the age of sixty-five, which, it is suggested, should be fixed as the compulsory retiring age. In the event of the death of a member before that age, arrangements would be made for payment to relatives, and there would also be payment out in the event of an employee ceasing to be a member of the fund.

In introducing the scheme to the Council, Alderman C. H. Wilson (Chairman of the Finance Committee) said he had been charged from time to time with inhuman conduct in having had to do with the scrapping of old men, and he had said before that they had made retiring allowances. They were still making such allowances; but the system seemed to be entirely one-sided. They had had to keep men who were absolutely inefficient, and that was not in the interests of anybody.

Alderman Wilson further said that the scheme was to be voluntary, and with regard to the forfeiture of payments for misconduct, an organised strike would not be deemed misconduct. He estimated the cost at a 2½d. rate, but he declared that this would be saved by stopping the retiring allowances, and by dealing differently with old servants.

It was decided to adjourn the consideration of the scheme until the next meeting of the Council.

We are informed that the Financial Committee of the French Senate have rejected the proposal for the Saturday half-holiday for State employees. The half-holiday for the latter employees had been promised by the Cabinet, and the President of the Republic had given the measure his support. The rejection of the measure may have far-reaching consequences.

The quarterly return, sent on the 29th ult., by the Board of Conciliation and Arbitration for the Manufactured Iron and Steel Trade of the North of England, to the Consett Iron Company, Limited, and Mr. Bradley, operatives' representative, relating to the wages to be paid at the Consett Works in the quarter beginning on Wednesday, the 1st inst., reads as follows :—

"We have received from Messrs. Price, Waterhouse and Co. the result of their ascertainment of the average net selling price of steel plates at Consett for the months of March, April, and May, 1914, and we hereby certify that, in accordance with the agreement entered into on March 30, 1898, the wages to be paid to the steel-millmen during the months of July, August, and September will be 2½ per cent. below the rate prevailing during the current quarter."

The men at Consett Works suffered a reduction of 5 per cent. in the quarter beginning March last, and their present wages are 15 per cent. above the standard. Their last advance of 2½ per cent. was in September last year, the wages then being 22½ per cent. beyond the standard; and in the December quarter the wages remained stationary.

The strike at the Copenhagen free harbour, which has lasted for more than half a year, has somewhat unexpectedly been terminated. Several attempts had been made to bring it to a close; the conciliator had done his best, but the men, contrary to the advice of the leaders, were stubborn, and tried to implicate the other harbour hands in the conflict. Renewed negotia-

tions among all the parties concerned have, however, resulted in an agreement, according to which the free harbour company consents forthwith to take back 200 of the men on strike on the same conditions as those in force for the other hands. Both parties undertake to do their best to enable work in the free harbour to progress amicably. The free harbour company has secured the right to keep 299 of the men engaged during the strike of the permanent hands, and a corresponding number of the old men will be without employment. On this point the men would have fared better had they accepted, instead of rejecting, the proposal put to them two months earlier.

NOTES FROM THE UNITED STATES.

PHILADELPHIA, July 1.

THE month of June has shown a general slight improvement in iron and steel. Price concessions are still made on attractive orders. We are entering on the mid-summer shut down. In many cases it will continue through most of this month or until new business justifies. Railroad buying has shown improvement. The Pennsylvania Railroad order has been reported as finally placed at 137,000 tons, 56,000 tons less than last year. No general improvement is expected until general confidence is stronger; notwithstanding the enormous crops about to be harvested, business drags. In pig-iron large producers are being offered contracts for future delivery at current prices, but in several instances these orders have been declined. The 70,000-ton pig-iron order for the New York subway has been finally placed with Pittsburgh and Buffalo foundries. The increased demand for foundry grades is affording encouragement. Basic pig, after several quiet weeks, is now active in the West. Rail orders for the week are 40,000 tons, besides a 10,000-ton order for export to Siam. Car-builders are doing better. Both plate and structural-steel makers are pleased with the volume of business made up of small orders. Bar iron has been shaded to 1.15 dols. Even at that, only necessary material for immediate use is bought. Further curtailment of pig-iron production is in sight. The New York Central Railroad is negotiating for 4000 cars, in addition to the 5300 recently placed. Negotiations are in progress to-day for 80 locomotives and 11,000 cars. The large Persian pipe-line order was taken, and work will soon begin. The pipe-foundries are all busy, and reports indicate a long continuance at maximum capacity.

THE SUEZ CANAL.—The report of the Suez Canal Company for 1913 states that ten years ago vessels with a displacement of more than 4000 tons each passing through the canal represented scarcely 22 per cent. of the total shipping dealt with; last year, however, the proportion rose to 44 per cent. Ships of upwards of 6000 tons displacement, ten years ago, represented only 1 per cent. of the aggregate amount; last year the proportion rose to 5 per cent. In 1912 the average time occupied by vessels in passing through the canal was cut down (by 35 minutes) to 16 hours 19 minutes, and this was maintained last year. The number of vessels which used the canal in 1913 was 5085. Last year, while the total trade done was less than in 1912, it showed a marked gain in the tonnage of loaded merchant ships, the quantity of merchandise carried being 25,775,000 tons, quite a record. The heaviest business was done east and south, and included coke from Great Britain, sugar from Adriatic ports, petrol from Russia and the United States, and phosphates from Algeria and Tunisia. A special feature was the size of the consignments to India and farther Eastern ports of worked metals, machinery, and railway material. Burma, Siam, Indo-China, and East Africa are increasing their trade with Europe, and the same may be said of China and Japan.

THE SAN FRANCISCO EXHIBITION.—The announcement is made that the United States Steel Corporation and its subsidiary companies propose to have a comprehensive exhibit at the Panama-Pacific Exposition in San Francisco in the year 1915. It will begin at the ore-fields and carry on an educative picture of its operations in ore-mining, rail and water transportation, dock operations, coal, coke and pig-iron production, steel manufacturing in its various lines, and will also illustrate the processes of manufacturing of many of its subsidiary companies' products; also how it utilises its by-products, showing many of the uses in which its general products are employed, typifying the advancement in the uses of the country's resources. In addition to these material exhibits the Corporation intends to exhibit in a comprehensive manner, by moving pictures, its operations throughout all departments, showing the ramifications of the processes of the Corporation. It is proposed as well to set forth to the world the work which the United States Steel Corporation has done towards the social welfare of its employees and those depending upon them. Also many forms of safety devices that have been devised by the Corporation officials and its employees. In this social welfare department will also be shown the methods employed by the Corporation for the aid and care of the injured, and the improvement of the employees' conditions at work, and the benefits that are aimed to be afforded to employees at their work and in their surroundings. Also the power that is given to the employees, through their committees, to bring about these improved working conditions and surroundings.

NOTES FROM SOUTH YORKSHIRE.

SHEFFIELD, Wednesday.

South Yorkshire Coal Trade.—A further improvement in the export demand has had a strengthening effect upon the hard-steam market, which, in consequence of local industrial weakness, was showing a somewhat irregular tendency. Since the conclusion of stock-taking the manufacturing demand has reverted to a normal condition. Among colliery-owners, however, there is wide complaint that the production is being seriously restricted, and working cost unnecessarily increased, because of miners absenting themselves from work. House coal is dull and weak. Prices continue to decline. The bulk of the yearly contracts, which are generally completed a month before the present date, are still outstanding. The Coal-Owners' Association is as determined as ever to maintain last year's advance, but it is evident that weakness exists somewhere, further contracts having been arranged at 6d. reduction. Slightly quicker progress is being made with renewals of gas-fuel contracts. Deliveries are being expedited so as to clear off arrears on expiring contracts. Slacks are not benefiting to the extent anticipated by the reduction in the house-coal output. Lower grades are very weak. For no class of coke is there more than a moderate demand. Quotations:—Best branch hand-picked, 15s. 6d. to 16s. 6d.; Barnsley best Silkstone, 13s. to 14s.; Derbyshire best brights, 12s. to 13s.; Derbyshire house, 10s. 6d. to 11s. 6d.; best large nuts, 10s. 6d. to 11s. 6d.; small nuts, 9s. to 10s.; Yorkshire hards, 11s. to 12s.; Derbyshire hards, 10s. 6d. to 11s. 6d.; best slacks, 7s. 6d. to 8s. 6d.; seconds, 5s. 6d.; smalls, 4s. to 5s.

Iron and Steel.—Another almost blank week has been experienced by South Yorkshire pig-iron vendors. Seeing that prices have touched what everybody appears to regard as a rock-bottom level, and that warrant stores are phenomenally low, a revival might be expected at any moment, but at present there is no indication of such a welcome change setting in. Against this is to be set the fact that bar-iron is almost unsaleable, and that there is very little necessity, therefore, to cover contracts. Present depression is seen at its worst in forge iron, which fluctuates greatly. Foundry iron is a more settled medium, and what few contracts have this week been arranged have chiefly been in this product. In both, however, the tendency is downwards. Derbyshire foundry is quoted at 9d. reduction on last month's figures, and Derbyshire forge at 1s. reduction. No further reduction has been made in the official price of Lincolnshire sorts. Though no great amount of business is passing in hematites, values are firm. The current figures are 73s. 6d. for West Coast and 68s. 3d. for East Coast hematite. Since the cessation of excessively hot weather and the completion of stock-taking, the output of steel has greatly increased. New business is now being booked in fairly satisfactory proportions, though there is a good deal of complaint at the size of the orders. There is no revival on home railway account, but requirements of foreign concerns are on a large scale. The activity at the big shipbuilding centres is also fairly reflected in the state of industry in the local engineering shops. Nothing has occurred to mar prosperity in the armament departments, which have substantial contracts on hand for almost every country in the world. Notably is this the case with Messrs. John Brown and Co., who have just completed their jubilee year with very satisfactory results. Makers of both crucible steel and steel billets are not too well placed for new business, but there is little to complain of in either the home or the overseas demand for edge-tools, mining and agricultural implements, or machinery. Steel alloys are a more profitable medium. Scrap, on the other hand, is a drug on the market.

THE DERWENT.—A meeting of a committee who have promoted an application to the Board of Agriculture for the formation of a drainage board for the Derwent Valley was held on Friday at York, to consider a report of Mr. R. F. Grantham, the Commissioner who held an inquiry into the application. Mr. Grantham has considerably modified the extent of the area proposed to be included under the board, but the area is still a workable one. The engineers appointed in connection with the scheme (Messrs. W. Fairbank and Co.) presented a report on the area suggested by the Commissioner, and a sub-committee was appointed to consider the question in connection with certain proposals as to the lower reaches of the river.

STEAM POWER USED FOR GENERATION OF ELECTRIC CURRENT IN PRUSSIA.—According to recent statistics, there were employed for the generation of electric current in Prussia steam-engines, portable and stationary, with a capacity of 1,410,000 horse-power, and steam-turbines used for the same purpose of 1,160,000 horse-power. As the total registered capacity of steam-turbines amounts to 1,240,000 horse-power, it will appear that 95 per cent. of the aggregate is used in the generation of electric energy. Altogether, 2,570,000 horse-power of steam-power are thus employed in the generating of electricity, and although it is a very substantial figure, it must be looked upon as minimum, inasmuch as many steam-engines used for this purpose are not included in the record. In addition to the above it must be remembered that a vast number of gas and oil-engines are used for the same purpose, in addition to water power; but of these there is no record. The largest total capacity of steam power used for generation of electric current is in the Arnsberg district with 389,898 horse-power, and the Dusseldorf district with an aggregate of 419,051 horse-power. Berlin-Potsdam comes next with 375,889 horse-power.

NOTES FROM CLEVELAND AND THE NORTHERN COUNTIES.

MIDDLESBROUGH, Wednesday.

The Cleveland Iron Trade.—A marked change for the better is noticeable, at all events so far as Cleveland pig-iron is concerned. This season is usually the quietest period of the year, but there are indications of revival, and several traders now take a much more cheerful view of the outlook, and speak hopefully of a brisk autumn business. The removal of the Russian import duty on pig-iron has brought more inquiries from that quarter than were looked for. One or two more sales to Russia are reported, and further business may follow, though Germany being so favourably geographically placed, will probably benefit most by the Russian concession. Values of Cleveland pig now show an upward movement. One or two small lots of No. 3 g.m.b. have realised 51s. 9d. f.o.b., and the general market quotation is fully 51s. 7½d.; whilst other qualities have also improved, No. 1 having become 54s. 1½d.; No. 4 foundry, 51s. 4½d.; No. 4 forge, 50s. 10½d.; mottled, 50s. 4½d.; and white, 50s. 1½d., all for either early or forward delivery. Better accounts are given of the East Coast hematite pig trade. Though a few contracts for mixed numbers are understood to have been made at rather less, it is now not probable that 59s. could be shaded, and that is the recognised market quotation for practically any delivery. Sellers report a fair amount of business put through at the foregoing quotation, and that buyers are much less disinclined to pay it than they have been. There is practically nothing passing in foreign ore, but prices tend downward, notwithstanding continued high freights, due largely to labour troubles. There are sellers on the basis of 17s. 3d. ex-ship Tees for Rubio of 50 per cent. quality, and consumers declare that they would have no difficulty in buying at the rate of 17s. Sellers of Durham coke show much reluctance to give way at all, but the position is a trifle easier, though the local demand keeps fairly good. For Durham blast-furnace coke, of average quality, 17s. 6d. is still asked for delivery at Teesside works, but business might be done at a trifle less. A good deal of Yorkshire coke is being taken up at comparatively low figures.

Stocks and Shipments.—The stock of Cleveland pig-iron in the public warrant stores here now stands at 78,653 tons—all of which is No. 3 quality. Since the beginning of the month the stock has been increased by 364 tons. Shipments of pig-iron from the Tees are on only a moderate scale. To-date this month they average 3015 tons per working day, the total despatches being returned at 21,105 tons, 19,458 tons of which have gone from Middlesbrough and 1647 tons from Skinningrove. To the same date last month, the loadings were given at 13,388 tons, or a daily average of 1912 tons, and for the corresponding part of July a year ago, the clearances reached 25,958 tons, or an average of 3708 tons per working day.

Manufactured Iron and Steel.—There are no new features of moment in the manufactured iron and steel trades. New orders are scarce. There are, however, orders on the market for rails, but they have not yet been allotted. Principal market quotations stand:—Common iron bars, 7*l.*; best bars, 7*l.* 7s. 6d.; best best bars, 7*l.* 15s.; packing iron, 5*l.* 5s.; iron ship-plates, 6*l.* 15s.; iron ship-angles, 7*l.*; iron ship-rivets, 7*l.* 5s.; iron girder plates, 7*l.* 5s.; steel bars (basic), 6*l.* 5s.; steel bars (Siemens), 6*l.* 5s.; steel ship-plates, 6*l.*; steel ship-angles, 5*l.* 15s.; steel boiler-plates, 7*l.*; steel joists, 6*l.* 12s. 6d.; steel strip, 6*l.* 5s.; steel hoops, 6*l.* 10s.—all less the customary 2½ per cent. discount; cast-iron columns, 7*l.* 7s. 6d.; cast-iron railway chairs, 4*l.* 5s.; light iron rails, 7*l.*; heavy steel rails, 5*l.* 15s. to 5*l.* 17s. 6d.; steel railway sleepers, 7*l.* 5s.—all net at works; galvanised corrugated sheets, 24 gauge, in bundles, 11*l.* 5s. f.o.b.—less 4 per cent.

Blastfurnacemen's Wages.—The ascertained net selling price of No. 3 Cleveland pig for the months of April, May, and June, has been certified at 51s. 0.70d. per ton, as compared with 51s. 5.13d. in the previous two months. This means a reduction in blastfurnacemen's wages of 0.50 (one-half) per cent., which brings the wages from 24.25 per cent. above the standard to 23.75 per cent. above the standard.

FRENCH TRANSATLANTIC NAVIGATION.—The working of the French General Transatlantic Company in 1913, after providing for reserve and redemption allocations, was attended with a profit of 94.852*l.*, as compared with a corresponding profit of 85,600*l.* in 1912 and 128,686*l.* in 1911. The balance available for 1913 admitted of a dividend of 7s. 2d. per share, 1251*l.* being carried forward.

THE ROAD BOARD—GRANTS TO HIGHWAY AUTHORITIES.—During the months of April, May, and June, 1914, the Road Board indicated additional advances to highway authorities, amounting in the aggregate to 340,112*l.*, of which 277,357*l.* was by way of grant, and 62,755*l.* by way of loan. The total advances made and indicated up to June 30, 1914, amount to 5,553,924*l.*—4,106,462*l.* by way of grant, and 1,447,462*l.* by way of loan. The formal advances by way of grant made, with the approval of the Treasury, during the last quarter, amounting to 267,436*l.*, were applied as follow:—

	£
Road crust improvements	231,753
Road widenings and improvement of curves and corners	24,016
Road diversions	5,125
Reconstruction and improvement of bridges ..	5,542
New roads and bridges	1,000

During the same period, advances by way of loan, amounting to the sum of 105,266*l.*, have been arranged.

RECENT DEVELOPMENT OF EXPRESS LOCOMOTIVES IN FRANCE.*

By Professor EDOUARD SAUVAGE, Member, of Paris.

Two papers on French locomotives by the author of the present one had the honour of discussion at the meetings of the Institution, one, in 1900, on "Recent Locomotive Practice in France,"† and the other, in 1904, on "Compound Locomotives in France."‡ This third paper, dealing with the further development, during the last decade, in the construction of locomotives for express service on French railways, has been prepared in accordance with the Council's desire. For the data and results of experience reported in this paper the author is indebted to the following chief engineers:—M. Lancrenon, of the Est; M Maréchal, of the Paris-Lyons-Méditerranée; M. Nadal, of the State; M. Asselin, of the Nord; M. Solacroup, of the Paris-Orléans; and M. Herdner, of the Midi, Railways, who with the greatest liberality provided him with all the necessary information.

With the exception of some "Atlantics," which are not likely to be reproduced, all engines built for this service since 1904 are six-coupled, either ten-wheelers (4-6) or "Pacifics" (4-6-2). Superheated steam is largely used, especially in the latest constructions. With a few exceptions the Schmidt standard superheater§ has been adopted. Owing to the large tubes necessary to receive the superheating pipes, it frequently happens when a superheater is fitted in a locomotive boiler that the proper heating or vaporising surface is greatly curtailed; in many engines the total of the heating and superheating surfaces is less than the heating surface which might have been obtained without superheating. The figures in Table I. give some examples of this reduction.‖

Without superheaters, the heating surface equals 72 to 77 times the grate area in the four first engines (narrow fire-boxes), and 60 to 62 times in the case of the last (wide fire-boxes). With superheaters, the ratio of proper heating surface to grate area is as low as 50 and does not exceed 60; and, with the exception of the two last engines and of Nos. 3601 to 3605 Paris-Lyons-Méditerranée, the

TABLE I.

—	Numbers.	Grate Area.	Heating Surface.	Superheating Surface.	—
		sq. m. sq. ft.	sq. m. sq. ft.	sq. m. sq. ft.	
Est (Eastern)	3103-3146 3191-3230	3.1607 (34.02)	234.91 (2528.59) 158.85 (1709.85)	37.25 (400.97)	47.37 sq. m. with "Mestre" suph. (509.90 sq. ft.)
P.L.M.	2606-2969 3601-3605 3691-3700	2.98 (32.072)	214.80 (2306.73) 160.90 (1731.89) 149.75 (1611-87)	57.15 (615.33) 33 63 (362.0)	With tubes of 70 mm. dia. (2.76 in.)
Etat (State	230, 571-230, 618 230, 619-230, 705	2.80 (30.14)	206.71 (2225.04) 159.50 (1716.88)	37.50 (403.66)	
Nord (Northern)	2641 2659	2.76 (29.71)	211.30 (2274.43) 164.13 (1766.7)	40.03 (430.89)	
P.O.	3501-3520 3521-3550	4.27 (45.96)	257.25 (2768.99) 210.97 (2270.84)	63.50 (683.53)	
Midi (Southern)	3001-3016 3051-3054	4.02 (43.27)	253.20 (2725.45) 216.29 (2328.12)	60.88 (655.33)	

total surface is reduced. Although the results in service are good in all cases of superheating, this large reduction of heating surface in some boilers cannot be entirely satisfactory.¶ No difficulty is reported to arise from the use of superheaters; they are easily kept in order; valves and pistons, properly lubricated with an efficient oil, do not give signs of undue wear, even with a high superheat, up to 340 deg. Cent. Except on one company, all engines for express service have four cylinders, with a large proportion of compounds; in a few cases, simple expansion in four equal cylinders is used, but the compound system appears altogether to be preferred. The one exception is the recent building, by the Midi Railway, of simple engines with only two cylinders, using superheated steam, for express service.* When superheaters have been added to the four-cylinder compounds, the diameter of the high-pressure cylinders has been increased, the low-pressure cylinders being left unaltered. Piston-valves are generally used on all cylinders, even on non-superheaters; but in a few cases—for instance, on Paris-Orléans engines—flat valves have been preserved on the low-pressure cylinders of superheaters.

The usual practice is to have four separate valve motions, of the Walschaert type, for the different cylinders of the compounds; the reversing-gear can operate at will the high-pressure and the low-pressure motions together, or only one of them. The starting device, when admitting steam directly to the low-pressure cylinders, opens a direct exhaust to the high-pressure. An exception is to be found on the Paris-Lyons-Méditerranée engines; the low-pressure valve-motion gives always the same admission (averaging 63 per 100) backwards and forwards; it is operated by the same screw as the high-pressure motion, but is only transferred from one position to the other when reversing. The high-pressure valve-motion being designed to give a very prolonged admission (up to 88 per 100), the starting device comprises only a cock admitting live steam into the low-pressure cylinders, without special exhaust for the high-pressure.

As regards details, it may be mentioned that, in some engines, the damper-box and doors that enclose in the smoke-box the collectors and ends of superheating pipes have been taken off. No inconvenience seems to result from this suppression. Trouble would arise from a prolonged use of the blower, which may be avoided. If further experience proves that this mechanism can be dispensed with, including the steam-cylinder for the automatic working of the damper, the saving in first cost and expenses for repairs will not be negligible, as well as the reduction in weight of about 300 kg. (660 lb.).† The driver's station, that used to be on the right side of the engine, has been transferred to the left. Bogie-wheels are, as a rule, braked.

TABLE II.—*Principal Dimensions of Recent 4-6 Locomotives, with Superheaters.*

† Serve ribbed tubes.

Two standard types of locomotives are used in France for express service, the ten-wheeler (4-6) and the "Pacific." Tables II. and III. give the particulars of the latest types of these two sorts of engines for the different railway systems.

Details on the practice of each railway system will complete this general view.

EST.

One hundred and thirty six-coupled express locomotives (4-6), four-cylinder compounds, with wheels of 2.090 m. (6 ft. 10.3 in.) diameter, are in service on the Est system. The two first (Nos. 3101-3102), erected in 1903, have been described in the 1904 paper on "Compound Locomotives" (page 362 and Fig. 10, Plate LIII.). They have been followed by:—

Nos. 3103-3128,	erected in	1906-7.
,, 3129-3150,	,,	1907-8.
,, 3151-3164,	,,	1909-10.
,, 3165-3190,	,,	1910.
,, 3191-3230,	,,	1912-13 (Fig. 1, page 47).

Nos. 3147 and following (eighty-four engines) are fitted with superheaters.

For the flat valves of the two first engines (Nos. 3101-3102), piston-valves have been substituted in all others. The diameters of the cylinders, 350 mm. (13.78 in.) and 560 mm. (22.05 in.), with 660 mm. (25.98 in.) stroke in these two engines, have been enlarged to 360 mm. (14.17 in.) and 590 mm. (23.2 in.). ; further, to 390 mm. (15.4 in.) for the high-pressure cylinders of the superheating engines (Nos. 3147-3230). Might not the low-pressure cylinders be enlarged, too, with advantage? But these cylinders, with their diameter of 590 mm. (23.2 in.), occupy the whole available space between the frames, and an increase of size would involve a radical change in the plan of the engine, which was not thought advisable.

Engines Nos. 3103-3164 have two steam-domes, but Nos. 3165 and following have only one.

Other systems of superheaters besides the Schmidt have been experimented upon. First, for fear of overheating the high-pressure cylinders, superheating in two stages was resorted to; high-pressure steam being moderately superheated, receiver steam passed a second superheater. This plan has been abandoned. A "helical superheater," on the principle of the Field tube, with ribs, was fitted to some engines, and was abandoned, too, on account of its insufficient surface and of the difficulty of cleaning its outside ribs. Another system is the Mestre squirrel-cage superheater, Fig. 2, page 47, which is working on some engines and gives ample surface.

It may be mentioned that in engines Nos. 3129-3146 the receiver comprises a number of large pipes in the smoke-box, with a heating surface of 7.736 sq. m. (83.3 sq. ft.), the object being to dry or even to superheat the low-pressure steam. This contrivance does not seem to have any well-marked effect. The ends of the superheating tubes, which are steel castings in Schmidt's system, come close to the fire-box, the distance being reduced to 550 mm. (21.7 in.). It has been found that these castings are rapidly covered with a slag deposit that protects them from a too intense heat. With the exception of the points mentioned, the several lots of these engines show but slight differences. The principal dimensions are given in Table II. The heating surface is computed on the side in contact with combustion gases; in the case of Serve tubes it is reckoned as the mean between the actual surface ribs included and the surface of a plain tube of the same inside diameter. The surface of the superheaters is the mean between their inside and outside surfaces.

As usual, the cylinders are provided with air relief-valves, which open automatically when steam is shut off; they are quite necessary with piston-valves unless Schmidt's by-pass be used. Some trouble having been experienced in the working of these valves, which must be large, they have been replaced by groups of six small ones (see Fig. 3, page 47). All wheels, bogie included, are fitted with brake-blocks. These engines have six-wheel tenders, holding 22 cub. m. (4850 gallons) of water and 8 tons of coal, weighing empty 20 tons.

Mr. Lancrenon, Chief Engineer of the Est Railway, declares these six-coupled engines give entire satisfaction. Although utilised mainly for fast trains, they can negotiate all passenger and even occasionally heavy goods trains. They attain easily the limit speed of 120 km. (74.6 miles) an hour, and run smoothly without injuring the track; the expenses for keeping up, as well as coal and water consumption, are moderate.

In addition to these express engines, the Est Railway's stock comprises 212 locomotives of a similar type, with wheels of 1.750 metres (5 ft. 8.9 in.), which may occasionally haul express trains. These engines have been mentioned in the previous papers on locomotives.* The "Atlantic" engines of the same company, described in the 1904 paper (Fig. 8, Plate 25), number only two, ordered for sake of comparison with the 4-6 engines.

As regards boiler pressure, the practice of the Est Railway is to reduce the maximum allowed by one unit, so as to be certain that this maximum is never exceeded. On boilers marked 16 kg. per sq. cm. (227.6 lb. per sq. in.) the safety-valves blow off at 15 kg. per sq. cm. (213.35 lb. per sq. in.).

PARIS-LYONS-MÉDITERRANÉE.

Since 1904 the Paris-Lyons-Méditerranée Railway ordered:—160 six-coupled bogie engines (4-6) from 1905 to 1909; 20 "Atlantics" in 1906; 177 "Pacifics" from 1909 to 1912; all with 2 m. (6 ft. 6.74 in.) driving-wheels.

To these may be added 170 ten-wheelers, with 1.80 m. (5 ft. 10.9 in.) wheels, ordered in 1910, and utilised on certain lines for express trains.

Of these 527 locomotives, 198 have superheaters; all have four cylinders, and are compounds, with the exception of 91 engines using superheated steam in four equal cylinders, on the simple expansion principle.

The 4-6 and the "Atlantic" locomotives were designed in 1904, with the same boilers and cylinders. Owing

* Paper read before the Institution of Mechanical Engineers at Paris, July 7, 1914.

† Proceedings of the Institution of Mechanical Engineers, 1900, page 375.

‡ *Ibid.*, 1904, page 327.

§ A description of the Schmidt superheater will be found in Mr. Flamme's paper, "Superheaters Applied to Locomotives on the Belgian State Railways" (Proceedings of the Institution of Mechanical Engineers, 1905, page 409, and Plates 15, 16, and 17). See also Mr. Fowler's paper, "Superheating Steam in Locomotives" (Proceedings of the Institution of Civil Engineers, 1913-1914).

‖ In France the heating and superheating surfaces are generally computed on the side in contact with combustion gases, including the whole surface of the ribs in the case of Serve tubes. An exception on the Est Railway will be mentioned. All measures in the present paper are metric, with the abbreviations adopted by the International Committee of Weights and Measures (Proceedings of the Institution of Mechanical Engineers, 1900, page 394).

¶ This question has been mentioned in F. H. Trevithick and P. J. Cowan's paper on "Some Effects of Superheating and Feed-Water Heating on Locomotive Working" (Proceedings of the Institution of Mechanical Engineers, 1913, Part II., page 345), but treated from a different point of view.

* Simple engines on the same principle exist on other railways, but not for fast service.

† When the damper is shut, the superheater elements lose their heat quickly, and take some time to regain it; this practically reduces the advantage of superheating for trains frequently stopping. For this reason the Midland Railway designed an apparatus to keep the doors open when the regulator is shut, provided the blower does not come into operation.

* Proceedings of the Institution of Mechanical Engineers, 1900, Fig. 12, Plate 46; and 1904, Fig. 3, Plate 50, and Fig. 9, Plate 52.

to the very good results obtained from the six-coupled, which have over the "Atlantics" the advantage of a greater adhesive weight, the building of engines of this latter class has been discontinued. Of these 160 ten-wheelers (Nos. 2601-2760), 10 (Nos. 2691-2700) have been built with an ordinary Schmidt superheater; 5 engines (Nos. 2601-2605), built in 1905, received later on a special Schmidt superheater, with small tubes and two collectors; these engines having Serve tubes of 70 mm. (2.76 in.) outside diameter, the superheating tubes found room in tubes of the same diameter without ribs.

In Nos. 2691-2700 (Fig. 4), built with superheaters, the diameter of the high-pressure cylinders has been increased from 340 mm. (13.39 in.) to 370 mm. (14.57 in.), the low-pressure cylinders remaining the same—540 mm. (21.27 in.). Of the five engines, fitted later on with superheaters, three only had their high-pressure cylinders increased, in view of comparative experiments. Table II. gives the principal dimensions of these engines.

A more powerful engine being wanted, a "Pacific" was designed in 1908, and 177 were put in service, in different lots, showing some differences. The main question to be resolved was whether, with superheated steam, simple expansion and a moderate boiler pressure and the net coal consumption (deduction made for lighting up) from 1.35 kg. (2.98 lb.) to 1.59 kg. (3.5 lb.). In some cases as much as 700 kg. (1543 lb.) of coal were shovelled in per hour and square metre (10 764 sq. ft.) of grate.

Compound locomotive 6204 hauled trains of 646 tons at an average speed of 80 km. (49.7 miles) to 90 km. (55.9 miles) an hour from Laroche to Blaisy; 2425 horse-power (2391 British horse-power) was indicated, and 1604 horse-power (1582 British horse-power) registered by the dynamometer on the pull-bar. The water consumed per hour and indicated horse-power varied from 6.13 kg. (13.51 lb.) to 6.82 kg. (15.03 lb.), the gross coal consumption from 1.03 kg. (2.27 lb.) to 1.22 kg. (2.69 lb.), and the net coal consumption from 0.933 kg. (2.06 lb.) to 1.08 kg. (2.38 lb.). The rate of combustion never exceeded 537 kg. (1183.9 lb.) per hour and square metre (10.764 sq. ft.) of grate.

Mr. Maréchal, Chief Engineer of the Paris-Lyons-Mediterranée Railway concludes: "The experiments show the compound locomotives at the same time more powerful and more economical than the simple. In consequence we discontinued the building of simple engines."

The 170 4-6 engines (Nos. 2430-2599) have the same general lines as the 2601-2760, but with smaller wheels, 1.800 m. (5 ft. 10.87 in.) instead of 2 m. (6 ft. 6.74 in.),

* Serve tubes.

were not as advantageous as the compound system with a higher pressure.

The two first "Pacifics," delivered in 1909, were a four-cylinder compound (No. 6001), to which a Schmidt superheater was added in 1913, and a four-cylinder simple (No. 6101), with superheater and pressure reduced to 12 kg. per sq. cm. (170.7 lb. per sq. in.); afterwards seventy similar simple engines (Nos. 6102-6171) were ordered, but it must not be inferred that the question of simple expansion *versus* compound was definitely settled, as the orders in 1912 comprise eighty-five four-cylinder compounds (Fig. 5, page 48) with superheaters (Nos. 6201-6285), and twenty four-cylinder simple engines (Nos. 6172-6191). In these last engines the boiler pressure was increased from 12 kg. to 14 kg. per sq. cm. (170.7 lb. to 199.1 lb. per sq. in.), as it was noticed that in the first engines the drop of pressure from boiler to steam-chest amounted frequently to 3 kg. per sq. cm. (42.67 lb. per sq. in.), owing to the presence of the superheater.

All "Pacifics" have plain tubes, without ribs, with an outside diameter of 55 mm. (2.17 in.), in relation with their great length, 5.50 m. (18 ft. 0.5 in.) and 6 m. (19 ft. 8.22 in.). The principal dimensions of these "Pacifics" will be found in Table III., above.

A tender holding 28 cub. m. (6180 gallons) of water and 5 tons of coal, carried on two bogies, has been designed for the "Pacifics." It weighs, empty, 28 tons.

Comparative trials of No. 6102 (simple) and No. 6204 (compound) took place between Laroche and Dijon, the line rising from Laroche to Blaisy (distance 132 km.) (82 miles) with long continuous grades of about 5 mm. per metre (1 in 200).

With trains weighing as much as 487 tons, locomotive 6102 (simple) indicated 2051 horse-power* (2022 British horse-power), the utilised power on the draw-bar being 1364 horse-power (1342 British horse-power). The water consumed per hour and indicated horse-power varied, in the different experiments, from 8.67 kg. (19.1 lb.) to 9.77 kg. (21.5 lb.), the gross coal consumption, including lighting up of fires, from 1.55 kg. (3.42 lb.) to 1.81 kg. (4 lb.),

* 1 French horse-power equals 75 kilogramme-metres (542.5 ft.-lb.) per second (32,550 ft.-lb. per minute).

boilers a little more powerful (grate area, 3.08 sq. m. (33.2 sq. ft.) against 2.98 sq. m. (32.1 sq. ft.)), heating surface, 239.64 sq. m. (2579.5 sq. ft.) against 214.30 sq. m. (2306.7 sq. ft.), cylinders of 370 mm. (14.57 in.) and 590 mm. (23.23 in.) against 340 mm. (13.39 in.) and 540 mm. (21.27 in.) with same stroke of 650 mm. (25.59 in.). The object was to have a powerful engine to haul express trains on difficult profiles, where the permanent way could not allow the running of "Pacifics." It will be noticed that these engines have no superheaters.

ETAT.

The express engines ordered by the State railways (formerly Ouest) since 1904, include 10 "Atlantics," built in 1905, 273 4-6 engines, and 108 "Pacifics."

The "Atlantics" are four-cylinder compounds, with cylinders of 360 mm. (14.17 in.) and 600 mm. (23.62 in.) by 640 mm. (25.20 in.), wheels of 2.040 m. (6 ft. 8.31 in.), grate area 3.10 sq. m. (33.4 sq. ft.), and heating surface 239.40 sq. m. (2576.9 sq. ft.).

Of the 4-6 engines, 108 (Nos. 230,511-230,618), built from 1904 to 1908, are similar to Nos. 2701-2720, described in the 1904 paper on compound locomotives (page 355 and Fig. 2, Plate 50), with unimportant differences; 87 (Nos. 230,619-230,705), built in 1908 and 1912, have a larger grate area, 2.80 sq. m. (30.14 sq. ft.), and Schmidt superheaters, the diameter of the high-pressure cylinders being enlarged to 380 mm. (14.96 in.). The heating surface is 158.50 sq. m. (1706.1 sq. ft.), and the superheating surface 37.50 sq. m. (403.7 sq. ft.).

Another lot comprises 58 engines (Nos. 230,801-230,858), built from 1908 to 1912, on about the same lines, but with smaller wheels, 1.850 m. (6 ft. 0.83 in.), instead of 1.940 m. (6 ft. 4.38 in.), a somewhat larger boiler and bigger cylinders, 360 mm. (14.17 in.) and 600 mm. (23.62 in.) by 640 mm. (25.20 in.), without superheat.

Nos. 230,781-230,800, with superheaters, Fig. 6, page 48, are simple-expansion engines, with four equal cylinders, 430 mm. (16.93 in.) by 640 mm. (25.20 in.). The principal dimensions are given in Table I.

Of the "Pacifics," two (Nos. 231,001-231,002), built in 1908, are four-cylinder compounds without superheaters, with wheels of 1.940 m. (6 ft. 4.38 in.). The fifty following ones (Nos. 231,011-231,060), equally four-cylinder compounds without superheaters (Fig. 7, page 48) have smaller wheels, 1.850 m. (6 ft. 0.83 in.), and date from 1910. The fifty-six, Nos. 231,501-231,556, four-cylinder compounds with superheat, are not yet in service. The wheel diameter of 1.940 m. (6 ft. 4.38 in.) has been reverted to. Piston-valves are used on the high-pressure cylinders and flat valves on the low-pressure. The same shape of grate as on the Paris-Orleans (Fig. 13, page 50), is used, narrow in front, wider in the back part, but with a half cylindrical outer shell, flush with the barrel, instead of the flat Belpaire top. The principal dimensions are given in Table III.

No precise experimental data, referring to the types of engines mentioned, are available. As regard the comparison of simple four-cylinder engines *v.* compounds, all with superheaters, the impression of some officials of the State railways seems to be in favour of the compound principle. Troughs for picking up water have been established close to Arnières, 115 km. (71.5 miles) from Paris on the Caen line, and 121 tenders are fitted with scoops; 56 more are in preparation.

NORD.

The locomotives used for fast trains on the Nord since 1904, all four-cylinder compounds, are:—

Thirty-five "Atlantics," the last fifteen of which (Nos. 2661-2675) have been built in 1904-5; 150 4-6 engines (Nos. 3513-3662), erected from 1909 to 1912; two "Baltic" engines (4-6-4), Nos. 3,1101-3, 1102, built in 1911; twenty "Pacifics" (Nos. 3,1151-3, 1170), built in 1912.

TABLE IV.

	"Atlantic" No. 2641 (Saturated Steam).	"Atlantic" No. 2659 (Superheated Steam).
No. and date of train	179, August 22, 1900	179, April 19, 1913
Weight of train	322 tons	356 tons
Average speed on level	107 km. an hour (66.5 miles)	113 km. an hour (70.21 miles)
Average speed on 5 mm. per m. (1 in 200) incline	90 km. an hour (55.9 miles)	93 km. an hour (57.8 miles)
Mean indicated power on level	1235 h.-p. (1217.7 h.-p.)	1435 h.-p. (1414.9 h.-p.) (increase 16, 2 p. 100)
Mean indicated power on 5 mm. (1 in 200) incline	1295 h.p. (1276.9 h.-p.)	1510 h.-p. (1488.9 h.-p.) (increase 16, 6 p. 100)
Water consumed per km. (0.621 mile) per ton-km.	Not measured	91.5 l. (20.13 gals.) 0.257 l. (0.057 gal.)
Coal consumed per km. (0.621 mile) per ton-km.	Not measured	16 kg. (35.27 lb.) 0.0449 kg. (0.099 lb.)
Duration of run, Paris-St. Quentin (153 km.) (95.1 miles)	1 hr. 35 min. 45 sec.	1 hr. 35 min.

Of the "Atlantics" twenty were in service before 1904, and have been described in the Proceedings of the Institution of Mechanical Engineers (1900, page 400, and Fig. 11, Plate 46; 1904, page 334, and Fig. 1, Plate 50*). To the new ones superheaters have been added; the heating surface, 211.30 sq. m. (2274.4 sq. ft.) was reduced to 164.13 sq. m. (1766.7 sq. ft.), with a superheating surface of 40.03 sq. m. (430.9 sq. ft.); the high-pressure cylinders have been enlarged from 340 mm. (13.39 in.) to 390 mm. (15.35 in.), the low-pressure remaining at 560 mm. (22.05 in.); pistons have been substituted for flat valves. Steam is admitted in the centre of the piston-valves of the high-pressure cylinders, and the valve-rods are at a greater distance from the piston-rods than with the flat valves. For these reasons the motion derived from the Walschaert gear is transmitted to the valve-rod by a combination of levers (Fig. 8, page 48), which may appear somewhat complicated, the motive being the desire to change as little as possible the design of the old engine. By a modification of the compensating beams, the adhesive weight has been increased from 33 tons to the new limit of 36. The results in Table IV. prove the advantage of superheating. With the normal weight of 250 tons for this train, the consumption per kilometre was 11.9 kg. (26.24 lb.) of coal and 83 litres (18.26 gallons) of water (0.0476 kg. (0.105 lb.) of coal per ton-km.), with superheat, against 13.7 kg. (30.20 lb.), and 109 litres (23.98 gallons) without (0.0548 kg. (0.121 lb.) per ton-km.). Thus the new engine shows an economy of 13.1 per 100 on coal, and 23.85 per 100 on water.

The 4-6 engines, with 1.750-m. (5-ft. 8.8-in.) wheels (Fig. 9, page 50), have been designed for express trains, weighing 350 tons and more, with frequent stoppages. They have the boilers of the "Atlantics," and the frames and motions of former 4-6 engines, Nos. 3078 3354.* The small diameters of wheels resulted from the necessity to keep down their weight, as a compensation for the increase due to the boiler; narrow limits per axle and per metre of length were not to be exceeded; at that time some bridges on the main lines, not yet renewed, could not allow heavier engines. Experience has proved that, even with that diameter of 1.750 m. (5 ft. 8.8 in.), provided the cylinder ports were large enough, speeds of 110 km. (68.4 miles) to 115 km. (93.2 miles) an hour were quite easy. These engines take frequently the place of "Atlantics," even with the faster trains, the only practical difference being a difficulty to attain a speed of 120 km. (74 6 miles) an hour.

The 57 first engines have cylinders of 350 mm. (13.78 in.) and 550 mm. (21.66 in.) by 640 mm. (25.20 in.) as the old Nos. 3078-3354, but the ports are 30 and 24 per 100 larger, being 35 mm. (1.38 in.) by 350 mm. (13.78 in.),

* Proceedings of the Institution of Mechanical Engineers, 1900, page 404, and Fig. 13, Plate 47.

instead of 35 mm. (1.38 in.) by 270 mm. on the high-pressure cylinders, and 40 mm. (1.58 in.) by 520 mm. (20.48 in.) instead of 40 mm. (1.58 in.) by 420 mm. (16.54 in.) on the low-pressure cylinders.* Balanced flat valves are used. The wheels have no splashers, the running-board extending above; a transverse foot-plate, as low as possible, behind the crank-axle, facilitates the visit and lubrication of the inside motion. A door is provided in front of the cab, on the right-hand side.

The 25 first engines use saturated steam; the 125 following (Nos. 3538-3662), erected since 1911, have Schmidt superheaters; their high-pressure cylinders have been enlarged from 350 mm. (13.78 in.) to 380 mm. (14.96 in.), and fitted with piston-valves of 200 mm. (7.87 in.) diameter, the valve motion being altered as on Fig. 8, page 48.

The principal dimensions of these engines will be found in Table II., page 45.

The six-wheeled tenders of some of these engines have been designed with a view of reducing, as far as possible, the firemen's work. As seen in Fig. 9, page 49, the coal-tank is entirely in front, with a bottom sloping at an angle of 45 deg. On both sides auxiliary tanks are provided for briquettes, which are also close at hand.*

Owing to the moderate diameter of the wheels, these engines may be used for every kind of service; they negotiate heavy goods as well as fast passenger trains. This has proved a great convenience on the Nord, where in autumn the goods traffic is enormous, whilst in summer and on holidays a large number of supplementary expresses, all heavy, have to be run. The figures in Table V., page 51, give a fair idea of the results obtained.

* In his paper on "Compounding and Superheating in Horwich Locomotives," Mr. George Hughes advocates large ports (Proceedings of the Institution of Mechanical Engineers, 1910, page 423).

* A description of this tender will be found in *Revue générale des Chemins de fer et des Tramways*, August, 1909, page 99, and Plate XIV.

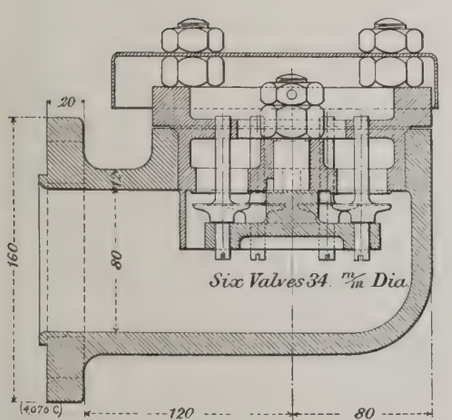

FIG. 3. SEXTUPLE AIR-RELIEF VALVES; EASTERN RAILWAY OF FRANCE.

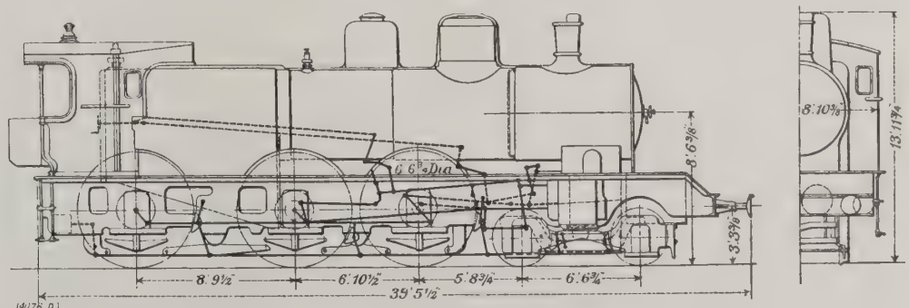

FIG. 4. LOCOMOTIVES NOS. 2601-2605 AND NOS. 2691-2700; PARIS-LYONS-MÉDITERRANÉE RAILWAY.

The two experimental engines, Nos. 3,1101-3,1102, called "Baltic," have been designed (in 1911) to haul weights of 400 tons at speeds of 120 km. (74.6 miles) an hour on the level, and 95 km. (59 miles) on 5 mm. (1 in 200) on their high-pressure cylinders instead of air-relief valves. After the results of experiments on the first of these engines, the section of the steam-pipes, the length of ports of high-pressure cylinders, and the travel of

The indicated power in regular working attains 1900 to 2000 horse-power (1972 British horse-power); 2120 horse-power (2090.52 British horse-power) has been registered once. With a train of 422 tons the speed has been in-

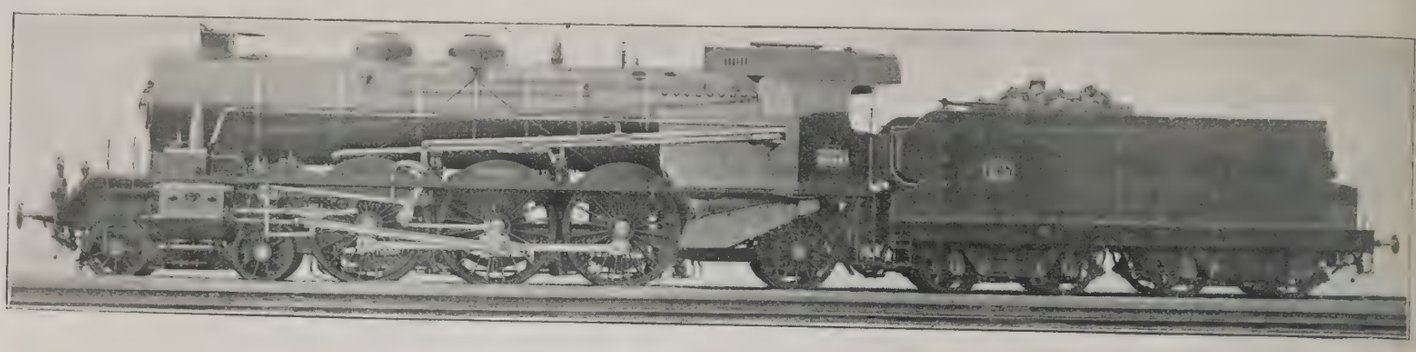

FIG. 5. LOCOMOTIVES NOS. 6201-6285; PARIS-LYONS-MÉDITERRANÉE RAILWAY.

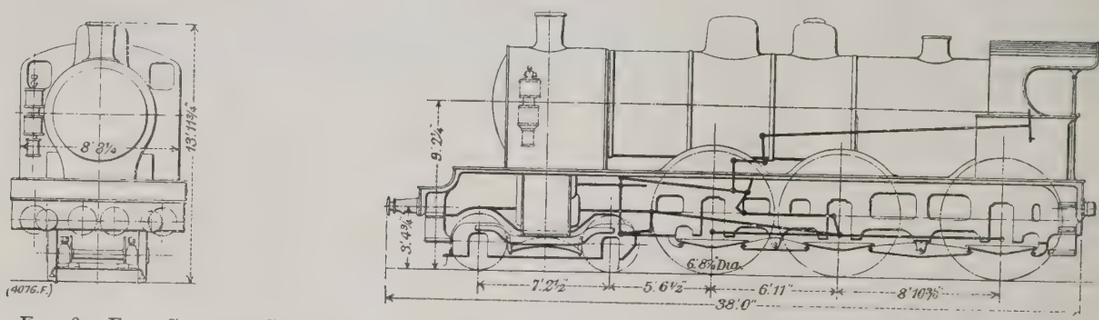

FIG. 6. FOUR-CYLINDER SIMPLE-EXPANSION LOCOMOTIVES NOS. 230,781-230,800; STATE RAILWAYS OF FRANCE.

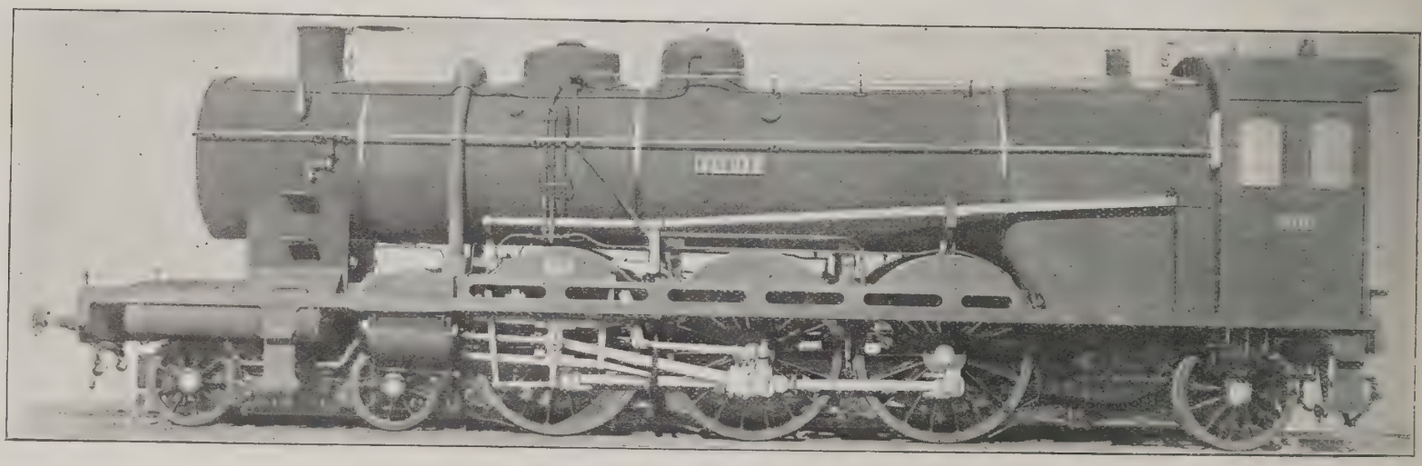

FIG. 7. "PACIFIC"-TYPE LOCOMOTIVES NOS. 231,011-231,060; STATE RAILWAYS OF FRANCE.

grades. These performances require an indicated power of 2200 horse-power (2170 British horse-power). The engine is carried on two bogies and six-coupled wheels of 2.040 m. (6 ft. 8.3 in.) diameter, Fig. 10, page 49. The lateral play of the front bogie is 50 mm. (1.97 in.), and of the rear bogie 120 mm. (4.72 in.). The principal dimensions are :—

Grate area	4.28 sq. m. (46.07 sq. ft.)
Heating surface ...	316.08 sq. m. (340.2 sq. ft.)
Superheating surface ...	70.00 sq. m. (753.5 sq. ft.)
Diameter and stroke, high-pressure cylinders	450 mm. (17.72 in.) by 640 mm. (25.20 in.)
Diameter and stroke, low-pressure cylinders	620 mm. (24.41 in.) by 730 mm. (28.74 in.)
Weight empty	103,200 kg. (227,510 lb.)
Weight in working order	113,010 kg. (249,140 lb.)
Weight, adhesive ...	55,510 kg. (123,380 lb.)

The two low-pressure cylinders inside the frames are, owing to their large diameter, one in front of the other, the distance between their axes being 385 mm. (15.2 in.) only.

The tender, carried on two bogies similar to the engine bogies, weighs empty, 25,210 kg. (55,600 lb.), and holds 26 cub. m. (918.2 cub. ft.) of water and 7 tons of coal. Table VI., page 51, gives the results obtained. It was not thought advisable to build more "Baltics" before a longer experience; for this reason 20 "Pacifics," Fig. 11 (page 49), began service at the end of 1912 with same diameter of wheels that the "Atlantics" had, but with a greater power and more adhesive weight. The principal dimensions of these "Pacifics" are given in Table III.

One peculiarity of these engines is the use of by-passes valves have been increased, with a notable gain of power. Two of the best performances, shown in Table VII., page 51, may be compared with the "Baltics."

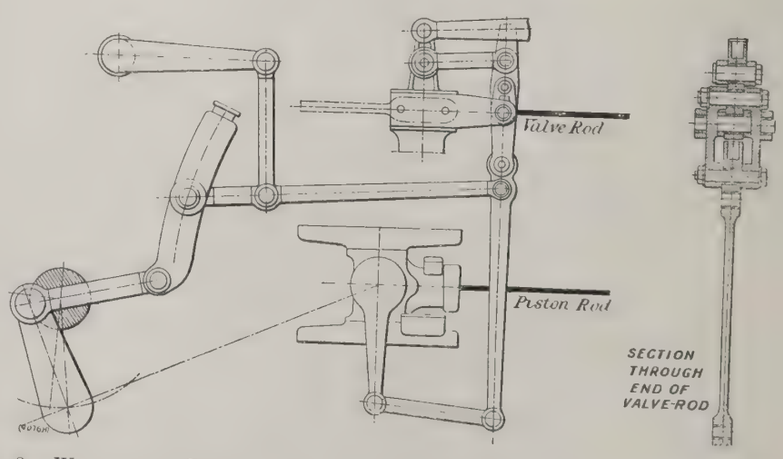

FIG. 8. WALSCHAERT GEAR FOR PISTON-VALVES WITH CENTRAL ADMISSION; NORTHERN RAILWAY OF FRANCE.

creased from 35 km. (21.7 miles) to 92 km. (57.2 miles) an hour on the 5 mm. (1 in 200) grade from St. Denis to Goussainville. On the 8-mm. (1 in 125) grade from

Marquise to Caffiers,* 8 km. (4.97 miles) long, the speed fell from 104 km. (64.6 miles) to only 75 km. (46.6 miles) an hour, with the same train.

As regards superheating, it has been adopted for all enced. The Nord engineers are of opinion that superheating and compounding must be combined.

The author cannot conclude better than by reproducing the terms of a letter from M. Asselin, chief engineer of 'Atlantics' by the addition of a superheater. Although taking heavier trains, these engines with superheaters showed an economy of at least 1.5 kg. (3.3 lb.) of coal per kilometre (0.62 mile).

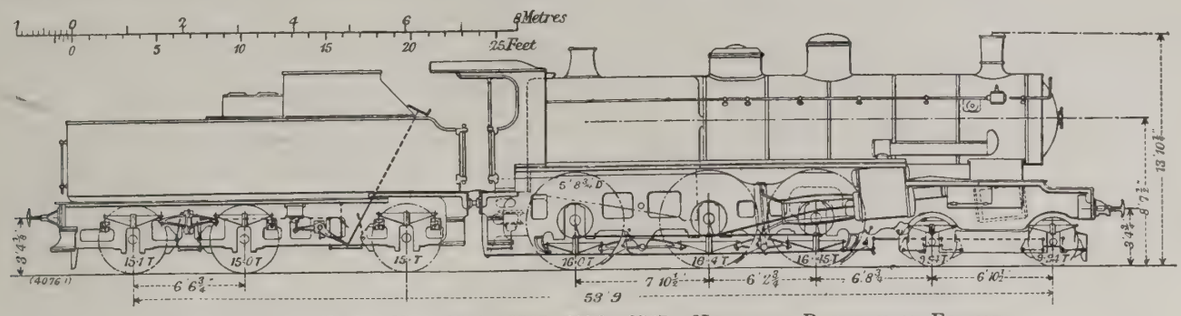

FIG. 9. LOCOMOTIVES NOS 2538—3567, 3578—3597; NORTHERN RAILWAY OF FRANCE.

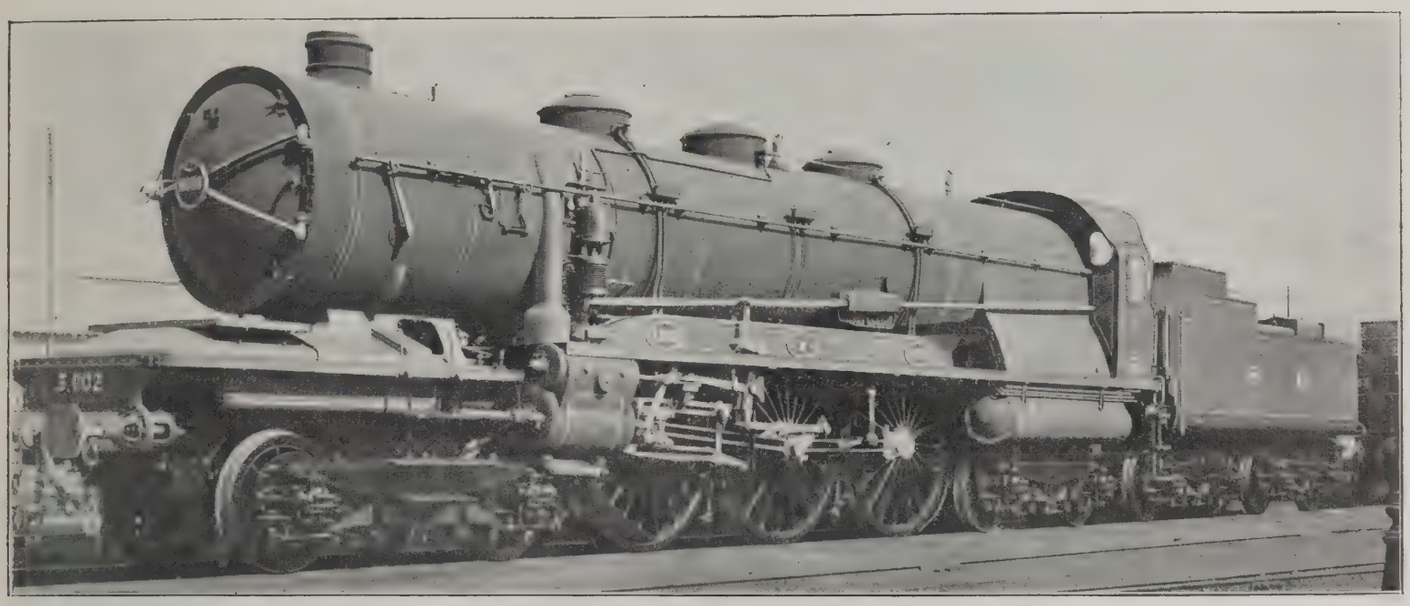

FIG. 10 "BALTIC"-TYPE LOCOMOTIVE; NORTHERN RAILWAY OF FRANCE.

recent Nord engines, and will be continued in future engines; with steam temperatures of 300 deg. to 340 deg. Cent. no undue expenses for repairs have been experienced. The Nord engineers are of opinion that superheating and compounding must be combined.

The author cannot conclude better than by reproducing the terms of a letter from M. Asselin, chief engineer of the Nord Railway, in which his experience is recorded in a perfectly clear and definite manner.

"Until 1904 our fast engine was an 'Atlantic' without superheater, four-cylinder compound, with a power of 1400 horse-power (1380 British horse-power).

"The first step was to increase the power of these 'Atlantics' by the addition of a superheater. Although taking heavier trains, these engines with superheaters showed an economy of at least 1.5 kg. (3.3 lb.) of coal per kilometre (0.62 mile).

"The second step was to build 'Pacifics' of about 1900 horse-power (1873 British horse-power). It is remarkable how these 'Pacifics' proved economical. With the same weights they consume practically the same quantity of coal as the 'Atlantics' with superheaters; and with heavier weight than the 'Atlantics'

* See Profiles in Proceedings of the Institution of Mechanical Engineers, 1904, Plates 55 and 56.

could manage without superheaters they burn less coal.

"I don't mention our two 'Baltic' engines, which are mere experiments. I cannot as yet consider any extension of that type of engine. As regards power they are far in advance of the 'Pacifics,' but far less economical. However, before long I shall be obliged to design locomotives more powerful than the present 'Pacifics.' The weight of our fast trains, which did not exceed 300 tons with the 'Atlantics' without superheaters, attains to-day regularly 400 tons, and frequently more—up to 450 tons. I must very soon examine the possibility of hauling 500-ton trains with the actual speeds.

"Will the new engines be 'Pacifics' or 'Baltics'? I cannot say. But it will be necessary to increase the boilers of the present 'Pacifics,' their grate area, and the diameter of the cylinders. The size of the boiler is limited chiefly by the weight allowed to each axle by the permanent-way department.

"To enlarge the grate area, the length of the grate will be increased to 3.50 m. (11 ft. 5.8 in.) or 3.70 m. "Pacifics" with 1.850 m. (6 ft. 0.8 in.) wheels (Nos. 4501-4600), and ninety with 1.940 m. (6 ft. 4.3 in.) wheels (Nos. 3501-3590), Fig. 12, Plate III. All are four-cylinder compounds; thirty of the first series and seventy of the last have Schmidt superheaters with enlarged high-pressure cylinders.*

The shape of the fire-box is quite peculiar; it extends over the back trailing wheels, but is contained between the last pair of drivers, Fig. 13, the object being to avoid a shallow box. Reports of the working of this style of fire-box are quite satisfactory. Owing to the great length of the tubes, 5.900 m. (19 ft. 4 in.) between plates, plain ones without ribs have been adopted, with an outside diameter of 55 mm. (2.17 in.). The necessity of increasing the diameter of very long tubes is obvious; but the reason why they are not of the Serve system is not evident. It may be that a sufficient heating surface being obtained with plain ones, it is better to avoid the increase in cost and weight of the ribbed tubes.

Piston-valves are used on the high-pressure cylinders, and flat valves on the low-pressure, even with superheated steam, and no trouble is reported. The main dimensions of these engines will be found in Table III. (page 46). They have six-wheeled tenders holding 20 cub. m. (706.3 cub. ft.) of water and 6 tons of coal.

Indicator diagrams on the superheating "Pacifics" made apparent a too high compression in the high-pressure cylinders, although the clearance was 13 per 100. This clearance being enlarged to the mean value of 20 per 100 for both sides, a smoother running was obtained without any increase of steam consumption†. Experiments with fast and heavy trains showed an indicated power up to 2180 horse-power (2099.5 British horse-power), and 1266 horse-power (1208 British horse-power) on the pull-bar behind the tender.

An interesting comparison was made in actual running of twenty "Pacifics" without and of fifteen with superheaters, taking in turn the same trains. The mean coal consumption per 100 ton-km. was, in winter, including steam heating of the trains:—

3.92 kg. (8.64 lb.) for engines without superheaters;
3.51 kg. (7.74 lb.) for engines with superheaters;

and in summer respectively:—

3.53 kg. (7.78 lb.) and 3.17 kg. (6.99 lb.).

These figures show an economy averaging 10 per 100 in favour of the superheat.

Special experiments on one engine with superheater showed a consumption of 0.97 kg. (2.14 lb.) to 1.12 kg. (2.47 lb.) of coal per indicated horse-power per hour. One kilogramme of coal evaporated from 7.87 kg. (17.4 lb.) to 6.82 kg. (15 lb.) of water, with rates of combustion of 299 kg. (659.2 lb.) to 430 kg. (948 lb.) per sq. m. (10.76 sq. ft.) of grate an hour.

M. P. Conte (in the paper mentioned in the footnote in previous column) gives an interesting record of the coal consumption of engines hauling the Paris-Bordeaux fast trains in successive years (see Table VIII., page 51).

The 340-ton trains hauled by "Pacifics" are fitted with Stone's lighting system, which increases slightly the coal consumption. It is well worthy of remark that in a period of fourteen years, although the weight of the train has been doubled, the coal consumption has remained nearly the same.

* An account of experiments on the superheaters by M. P. Conte has been published in the *Revue Générale des Chemins de fer et des Tramways* in June, 1912.

† Compare Mr. G. Hughes's opinion, who advocates shorter periods of compression in preference to increased clearance volume (Proceedings of the Institution of Mechanical Engineers, March, 1910, page 401).

PARIS-ORLÉANS.

Since 1904 the Paris-Orléans Railway has ordered 100

MIDI.

During the last decade the Midi Railway has added to its stock the following numbers:—

In 1905, six "Atlantics," Nos. 1911-1916, four-cylinder compounds, similar to the ten engines mentioned in the 1904 paper (page 333); four of these engines will receive a Schmidt superheater.

In 1906-1907, fourteen other "Atlantics," Nos. 1921-1934, with a longer grate, 3.08 sq. m. (33.2 sq. ft.), instead of 2.78 sq. m. (29.9 sq. ft.), and same cylinders, 340 mm. (13.39 in.) and 560 mm. (22.05 in.) by 640 mm. (25.20 in.).

In 1908-10, sixteen "Pacifics," Nos. 3001-3016, four-cylinder compounds, with the following dimensions:—

Grate area	... ...	4.02 sq. m. (43.3 sq. ft.)
Heating surface	...	253.20 sq. m. (2725.5 sq. ft.)
Steam pressure		...16 kg. per sq. cm. (227.6 lb. per sq. in.)
Cylinders, diameter	...	370 mm. (14.57 in.) and 620 mm. (24.41 in.)
Cylinders, stroke	... ...	650 mm. (25.59 in.)
Driving wheels, diameter	...	1.940 m. (6 ft. 4.3 in.)

In 1910, four similar "Pacifics," Nos. 3051-3054, with the addition of a Schmidt superheater of 60.88 sq. m. (655.3

sq. ft.), reducing the proper heating surface to 216.29 sq. m. (2328.1 sq. ft.), this proportion being ampler than in many cases mentioned before; the diameter of the high-pressure cylinder has been enlarged to 400 mm. (15.8 in.).

TABLE VII.

No. and date of train	No. 5, Feb. 26, 1914	No. 115, Feb. 28, 1914
Weight of train .. .. tons	430	356
Average speed on level km. per hr.	110 (68.35 miles)	112 (69.56 miles)
Average speed on 5 mm. (1 in 200) incline .. km. per hr.	90 (55.92 miles)	90 (55.92 miles)
Water consumed per km. l.	118 (25.96 gals.)	No measurement.
Water consumed per ton-km. l.	0.275 (0.061 gal.)	
Coal consumed per km. kg.	19.2 (42.33 lb.)	No measurement.
Coal consumed per ton-km. kg.	0.0446 (0.098 lb.)	
Duration of run, Paris-Calais, 298 km. (185.17 miles)	3 hours 15 min. (including 5 min. stop at Abbeville)	—
Duration of run, Paris-St. Quentin 153 km. (95.07 miles)	—	1 hour 36 min.

In 1910-1912 comes in service a new type of 4 6 engines, Nos. 3501-3516, where advantage is taken of the superheater to reduce the boiler pressure to 12 kg. per sq. cm. (170.7 lb. per sq. in.), and to revert to simple expansion in two cylinders only of 590 mm. (23 2 in) by 640 mm. (25.2 in.), Fig. 14, page 50. The diameter of wheels is reduced to 1.750 m. (5 ft. 8.8 in.); the principal other dimensions will be found in Table II. (page 45). Owing to the good results obtained from these engines, four "Pacifics" on the same plan, Nos. 3101-3104, have been designed, and are in course of construction, with a boiler pressure of 13 kg. per sq. cm. (184.9 lb. per sq. in.), two cylinders of 630 mm. by 650 mm. (24.80 in. by 25.59 in.), and wheels of 1.940 m. (6 ft. 4.3 in.), Table III.

We may mention here, as used for express trains on mountain lines, six tank engines, Nos. 4501-4506, put in service in 1913, with four-coupled axles and bogie, having the following dimensions:—

Grate area ...	...	3.19 sq. m. (33.37 sq. ft.)
Heating surface	...	163.16 sq. m. (1756.2 sq. ft.)
Superheating surface	...	45.26 sq. m. (487.12 sq. ft.)
Boiler pressure ...	...	12 kg. per sq. cm. (170.68 lb. per sq. in)
Cylinders (2), diameter		630 mm. (24.80 in.)
,, ,, stroke	...	640 ,, (25.20 ,,)
Diameter of wheels	...	1.600 m. (5 ft. 2.9 in.)
Weight, empty...	...	74,000 kg. (72.8 tons)
,, in working order		93,500 ,, (92 tons)
,, adhesive	...	70,500 ,, (69.4 tons)

The author is indebted to M. Herdner, chief engineer of the Midi, for the comparison of simple superheaters and compound non-superheaters, Table IX. This comparison results from practical working of the same trains during periods of nine to ten months, and is specially interesting in the second case, where similar "Pacifics" ran in parallel. In the first case the "Pacifics," weighing 90 tons, with their grate area of 4.02 sq. m. (43.3 sq. ft.), ran against 4-6 engines of 76.3 tons, with grate area of 2.78 sq. m. (29.9 sq. ft.), which were likely more appropriate to the not very heavy trains.

In his elaborate paper, "Compounding and Superheating in Horwich Locomotives,"* Mr. G. Hughes comes to similar conclusions.

As pointed out by Mr. J. A. F. Aspinall † and by Mr. G. Hughes in his 1910 paper, the coal bill is only one item of expense in locomotive working, although the rise in the price of coals makes it more and more important; the economy of first cost in the case of two-cylinder simple engines must be taken into account. It will be of great interest to analyse in the long run as far as possible the new practice of the Midi.

TABLE VIII.

Date.	Type of Engine.	Weight of Train.	Coal Consumed from Paris to Tours. Per Ton of Train.	Total.
		tons		
1897	Forquenot, 2-4-2	175	18 48 kg. (40.74 lb.)	3235 kg. (7130 lb.)
1902	Four-cylinder compound, 4-4	219	15.63 kg. (34.46 lb.)	3424 kg. (7549 lb.)
1906	"Atlantic," four-cylinder compound	234	12.83 kg. (28.28 lb.)	3002 kg. (6618 lb.)
1911	"Pacific" without superheater	340	11.28 kg. (24.87 lb.)	3835 kg. (8454 lb.)
1911	"Pacific" with superheater	340	10.54 kg. (23.24 lb.)	3583 kg. (7899 lb.)

TABLE IX.

Engines.	Average Mileage per Month.	Average Weight of Train Alone.	Coal Consumed. Per Kilometre.	Per Ton-Kilometre of Train Alone.
		tons		
Simple superheaters, Nos. 3501-3516	8262 km. (5133 miles)	225	11.646 kg. (25.662 lb.)	0.0522 kg. 0.115 lb.)
4-cylinder compound non-superheaters, Nos. 3001-3016	8181 km. (5083.4 miles)	235	13.866 kg. (30.57 lb.)	0.0623 kg. (0.137 lb.)
2-cylinder superheater, "Pacifics," Nos 3051-3054	8150 km. (5064.2 miles)	255	14.100 kg. (31.09 lb.)	0.0563 kg. (0.124 lb.)
4 cylinder compound non-superheater, "Pacifics" Nos. 3001-3016	8140 km. (5058 miles)	252	14 616 kg. (32.22 lb.	0.0591 kg. (0 130 lb.)

The above descriptions make apparent the large increase in the power of express locomotives, which is characteristic of recent constructions; nevertheless, a further increase will be required in a near future. To meet the severe requiremets of traffic, larger boilers have been designed and fitted with superheaters. This state of affairs seem to be the same in Great Britain and in France. In both countries special experiments as well as ordinary practice have proved that superheating confers an important increase of power without causing trouble or undue expenses. Another point on which experts agree is that superheating alone is equal to or even better than compounding with saturated steam.

One point that seems open to further discussion is whether superheating and compounding must be superposed. In general, French practice as regards express engines is in favour of this superposition, with the interesting exception of the Midi Railway.

APPENDIX.

Descriptions and tracings of some of the locomotives mentioned above will be found in the following periodicals:—

COMPOUND ARTICULATED LOCOMOTIVES.‡

By ANATOLE MALLET, of Paris.

THE author asks permission to recall that at the summer meeting of the Institution, held in Paris in 1879, he explained the applications which he had made of double-expansion to locomotives He is pleased he is able (35 years afterwards) to explain a particular type of compound locomotive at a similar meeting.

If rack lines, whose total length is not over a thousandth of that of railways all over the globe, be neglected, one may say that traction takes place solely through adhesion—that is, through friction between the rails and the tyres of the wheels under the action of the weight bearing on the axles. Friction is, after all, the universal principle of self-propelled locomotion on earth. Animals are able to walk because their feet have a grip on the ground, while others crawl on their stomachs. If the gradient is too severe, animals, such as those which Nature has provided with claws, make use of them to support themselves without fear of slipping—a process which has been copied in the rack. The only thing is that in beings the progress in intermittent, whereas mechanical progress takes place in a continuous way, by means of wheels.

The tractive force of a locomotive is equal to the weight brought to bear on the rails by the tyres of driving and coupled wheels multiplied by the coefficient of friction for the parts in contact. This total weight is equal to the product of the number of coupled axles and the load on each axle (the latter load depending upon the conditions of settlement of the track) This weight, which was 3 tons per axle in 1825 on the Stockton to Darlington line, when railways were first started, increased to 8 tons in 1842, 14 tons in 1855, 16 tons in 1890, and has now reached about 20 tons (on the more important lines, of course). In the United States the weight goes up to 25 tons and more. For a long time, three was the maximum number of axles coupled together, whereas now four and even five axles are coupled, and only recently (though it was exceptional) six axles were reached. One can give a striking idea of the increase in weight and tractive power of engines for the last 85 years, from the point of view of utilising the track, in this way. (The author believes that this has not been published before.)

In 1829 an engine with two axles coupled, running on rails 17 kg. per metre (34.2 lb. per yard), weighed 5 tons, which was equal to 300 times the weight of rails per metre.

In 1846 an engine with three axles coupled, weighing 22 tons, ran on rails 35 kg. per metre (70.52 lb. per yard). This came to 630 times the weight of rails per metre.

In 1880 an engine with four axles coupled, weighing 56 tons, ran on rails 42 kg. per metre (84.6 lb. per yard). This came to 1330 times the weight of rails per metre.

In 1911 a six-axle-coupled Golsdorf engine, weight 96 tons, on rails 48 kg. per metre (96 77 lb. per yard), gave a ratio of 2000. In 1911, as well, in the United States, a Mallet engine with ten axles coupled, weighing 245 tons (adhesive weight), represented a ratio of 4600 times the weight of rails of 55 kg. per metre (111 lb. per yard); but this ratio, which is very high, is due, to some extent, to an exceptional weight per axle which is not to be found outside the United States.

If adhesive force be taken as one-sixth of the weight, it will be found that the ratio of the tractive force at wheel tread to the weight of rails per metre has varied according to the values: 50—105—225—333—750.

The number of coupled axles, when coupling by outside rods requires that the axles must be absolutely parallel, is limited by the minimum radius of the curves on the line. In fact, for a certain radius there is a maximum distance between extreme parallel axles which must not subtend an angle greater than about 1 deg. Beyond this, friction between the flanges of the wheels and the edge of the rails gives rise to severe wear of the surfaces in contact, and there is a chance that the flanges might jump the rails and cause derailments. It is true the flanges can be greased, but that is rather a poor solution of the problem.

When the required tractive force necessitates an adhesive weight which, in view of the profile of the line and of other conditions, is greater than what the maximum number of coupled axles could bear, special assistance is required, such as pushers, two engines, motor driving wheels on tenders, twin-engines or articulated engines. In articulated engines one can easily obtain the same adhesive weight (that is, the same tractive force) as with two engines, by distributing the axles on two frames coupled together, but capable of moving at an angle to one another, on curves. Such an engine with six axles will, for example, take the same curve of minimum radius as would fit an ordinary engine with three axles coupled. This type of engine comprises rather a large number of different models, all of which have, as a common characteristic, an absence of enforced parallelism between the two groups of axles. But these types can be arranged into distinct categories, which rest partly on the number of cylinders driving the wheels and partly on the disposition of the frame of the wheels, so that, if these different categories be taken two by two, one gets the following four classes:—

1. Locomotives with two movable trucks and only one set of cylinders.
2. Locomotives with two movable trucks and two sets of cylinders.
3. Locomotive with only one truck and one set of cylinders.
4. Locomotive with only one truck and two sets of cylinders.

The author will examine classes 2 and 4, because categories 1 and 3 are based on the use of certain mechanical transmissions, which, alone, would be a subject for a special paper.

Locomotives with two trucks and two sets of cylinders first appeared in the United States in 1832 in a somewhat primitive form, due to Horatio Allen. But at the Soemmering competition in 1851 locomotives of this type were seen built on a practical plan. These engines were: the Seraing, built by the Belgian firm of the same name, with two barrels and two central fire-boxes, weight 56 tons; and the Wiener-Neustadt, built by W. Gunther, of Vienna, with a single boiler, weight 61 tons, with full supply of fuel and water. The Seraing happens to be the prototype of the Fairlie engine, so far as essential

* Proceedings of the Institution of Mechanical Engineers, March, 1910, page 399.

† Ibid, 1900, page 408.

‡ Paper read before the Institution of Mechanical Engineers at Paris, July 7, 1914.

dispositions are concerned, in the same way as the Wiener-Neustadt is the prototype of the Meyer engine. It is absolutely necessary to distinguish clearly between the characteristics of these different engines. In fact, the author has had occasion to note that mistakes are made daily with regard to this, and they are even found in well-known works. Thus we read in a book on locomotives, published in London in 1907, that the Mallet engine is nothing but the Meyer engine, which appeared in 1867, to which M. Mallet had applied double expansion in 1884!

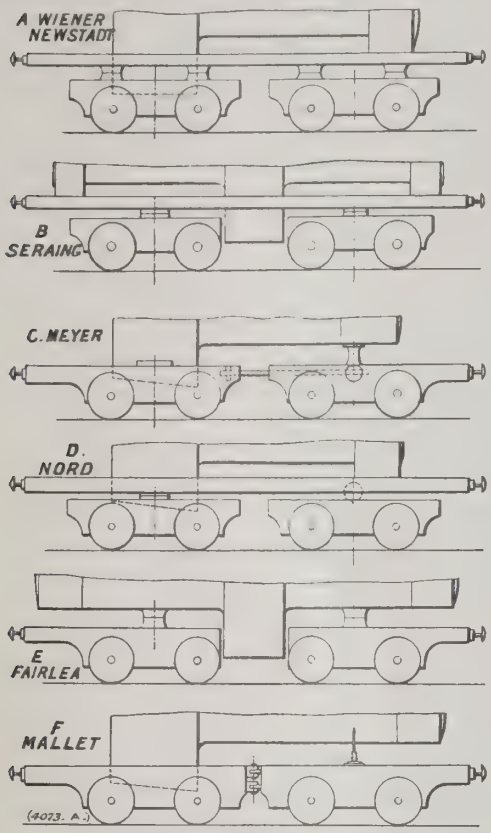

FIG. 1. CHARACTERISTICS OF SEVERAL TYPES OF TWO-TRUCK ARTICULATED ENGINES.

So that the author thinks he should give diagrams, Fig. 1, showing the essential characteristics of each of these types, including the engine of the Chemin de fer du Nord, constructed in 1904 by the late M. Du Bosanquet. The author will only casually mention the Garatt engine, which is characterised by the very great distance between the two driving-trucks, thus allowing the boiler to be lodged between them, so that it may be fixed much lower, and have a greater width than in the other types, where it is above the trucks.

The characteristics of the engines are as follow:—

(A) *Wiener-Neustadt.*—Main frame, carrying buffing devices and driving apparatus, and resting on the trucks on supports shaped horizontally like circular arcs—single boiler.

(B) *Seraing.*—Main frame, carrying buffing devices and driving apparatus, and resting on the trucks on lateral supports; the central points are independent of the coupling device. The boiler has a double central fire-box and double cylindrical barrel.

(C) *Meyer.*—No main frame—the buffing devices and driving apparatus are carried by the trucks—the single boiler rests on the back truck on lateral supports, and on the front truck on a spherical pivot; the two trucks are coupled by means of an arrow.

(D) *Nord.*—Main frame, carrying buffing devices and driving apparatus, and resting on the back truck on lateral supports, and on the front truck on a spherical pivot. Single boiler.

(E) *Fairlie.*—No main frame—the buffing devices and driving apparatus are fixed on the trucks—and the boiler, which has a central fire-box and two cylindrical barrels, rests on the trucks on circular supports, which also serve as couplings and have a certain elasticity laterally.

(F) *Mallet.*—This engine differs essentially from the others in that it has only one truck, placed in front, and joined at the back to the main frame of the engine by a king-pin. The front of the boiler rests on the truck on supports in the shape of arcs, whereas the back is fixed to the main frame.

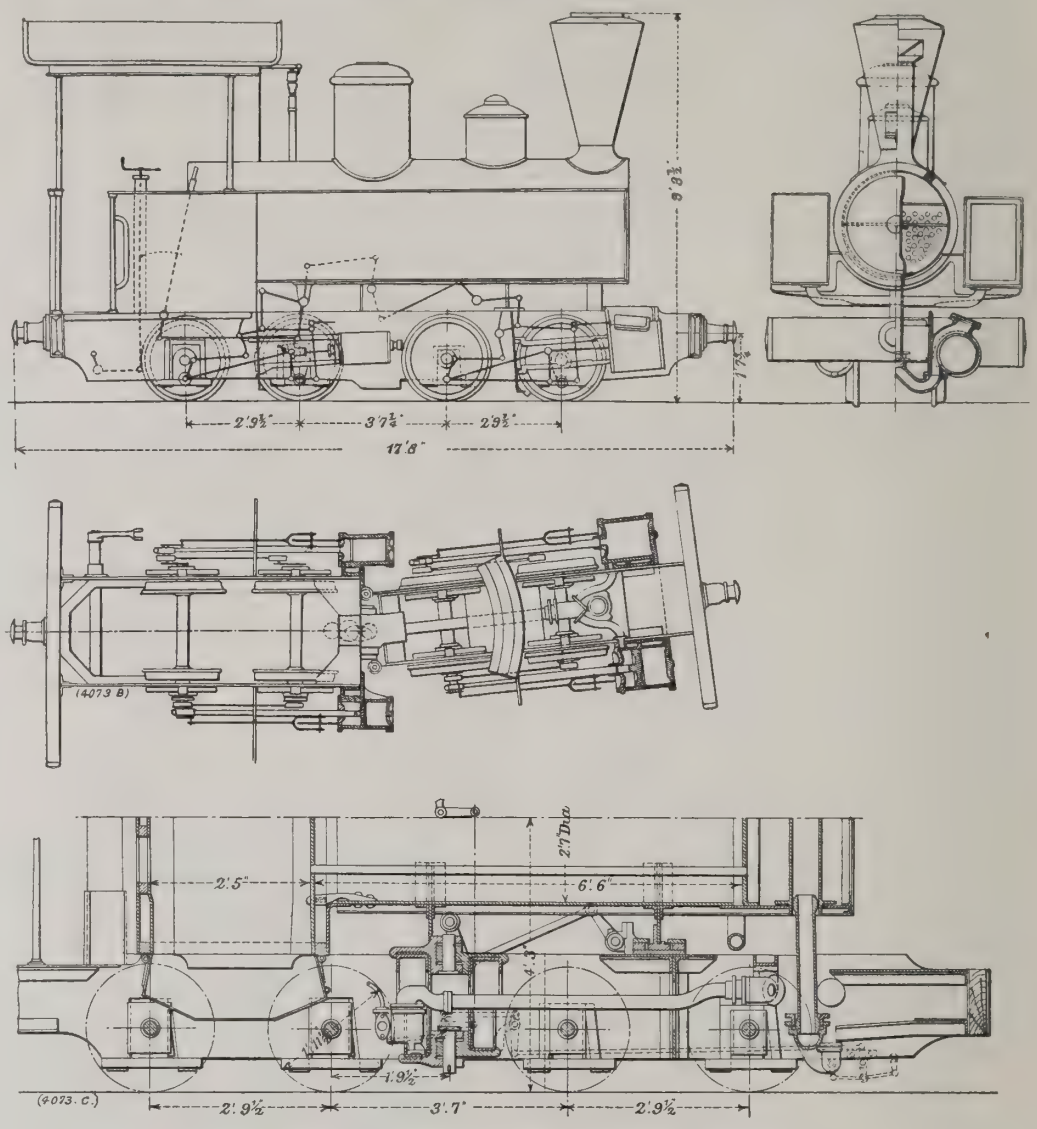
The author, in studying this type, reasoned on the following principle:—An engine, with two axles coupled, driven by two cylinders, and resting in front on a bogie with two axles as well, takes curves easily, but only part of its weight can be utilised for adhesion, and it cannot therefore exert a tractive force corresponding to its whole weight.

If the wheels of the truck be driven by a pair of low-pressure cylinders of convenient size fixed to the truck, and if these cylinders be fed by the steam coming from the back high-pressure cylinders, a simple method will have been arrived at, giving the three following results:—

1. The engine will have been allowed the full benefit of its weight for adhesion, and at the same time it will have great flexibility.

2. The main difficulties which arise in the case of the Fairlie and Meyer types, and other types with two trucks, will have been removed in so far as the movable tubing of the new engine (which tubing is, after all, much less intricate than the other) will only take steam which has already been expanded to a pressure of 3 kg. to 4 kg. per sq. cm. (42 lb. to 57 lb. per sq. in.) at most.

3. A rather simple type of locomotive will thus have been created which is justified by several advantages, to be referred to later.



FIGS. 2 AND 3. LOCOMOTIVE FOR DECAUVILLE RAILWAY.

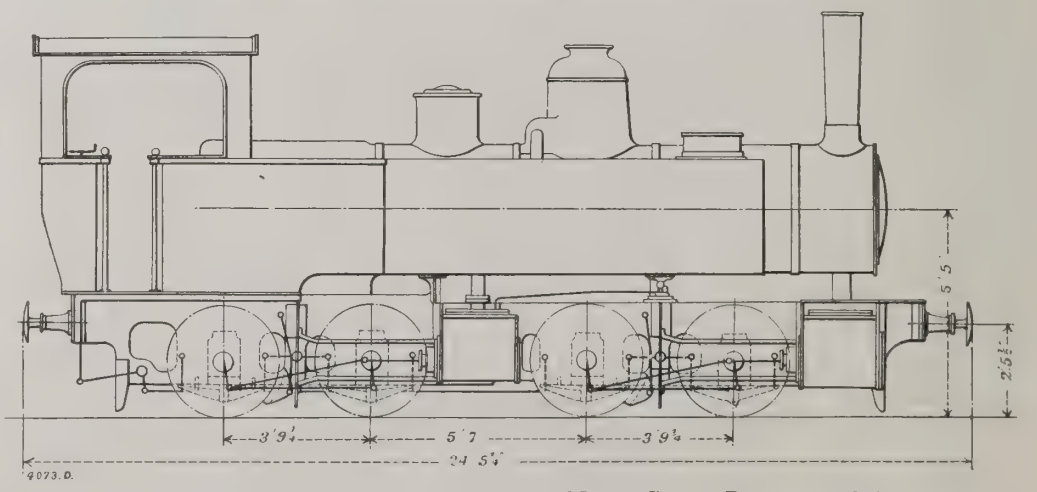


FIG. 4. LOCOMOTIVE FOR DEPARTMENTAL METRE-GAUGE RAILWAY, 1888.

This system, which the author advocated as far back as 1884, fulfilled the following conditions laid down by the Decauville firm in 1887 for locomotives running on 0.50 metre (1 ft. 11½ in.) tracks:—

The engine had to take grades up to 1 in 12.5 and haul weights nearly equal to its own, take curves of 20 metres in radius, and not weigh above 3 tons per axle, or 12 tons for four axles.

Figs. 2 and 3, above, show this engine. It is carried on four axles, two at the back under the fixed portion of the engine and two in front under the Bissel truck, which articulates round a vertical hinge. The barrel of the boiler rests on the truck in a slide working in a circular groove carried by the truck as shown in plan in Fig. 2. The back cylinders work at high pressure, and the steam comes direct from the boiler. After having done its work, the steam goes to a central box containing a pipe curved in the shape of a swan's neck, Fig. 3, which can turn round in that box, and the horizontal part of which proceeds to the front, where, through an up-take to be seen on the plan, it carries the steam to the low-pressure cylinders placed on the fore truck.

The steam then escapes from these cylinders through a vertical pipe, which carries a knee-cap socket at its base, so that, with the aid of this combination, the high-pressure steam goes through fixed tubes only as in ordinary engines, and the pipes with movable joints take expanded steam only. This is very satisfactory, so far as tightness of joints is concerned, and presents great facilities for the use of superheated steam in those engines. The success of that first engine was complete, and the Decauville firm built a large number of them, which were sent to different countries to be used on agricultural farms, and on mining and forest works, but the most important application was at the Universal Exhibition of 1889 in Paris, where six of those engines

did the traffic on the Inner Circle of 0.60-metre (1-ft. 11½-in.) gauge laid down by the Decauville firm. They covered a total distance of 113,000 km. (72,000 miles), and carried more than 6,000,000 passengers with regularity and without accident.

The author wishes to recall that on July 6, 1889, he had the pleasure of showing, at the "Petit Bourg" on four axles, weighing 60 tons (in running order), and one on six axles, weighing 85 tons. These tank-engines built for a normal gauge were intended: The first for the Swiss Central Railway, and the second, Fig. 5, for the St. Gothard Railway. This second engine was then the heaviest engine in the world—the United States excepted.

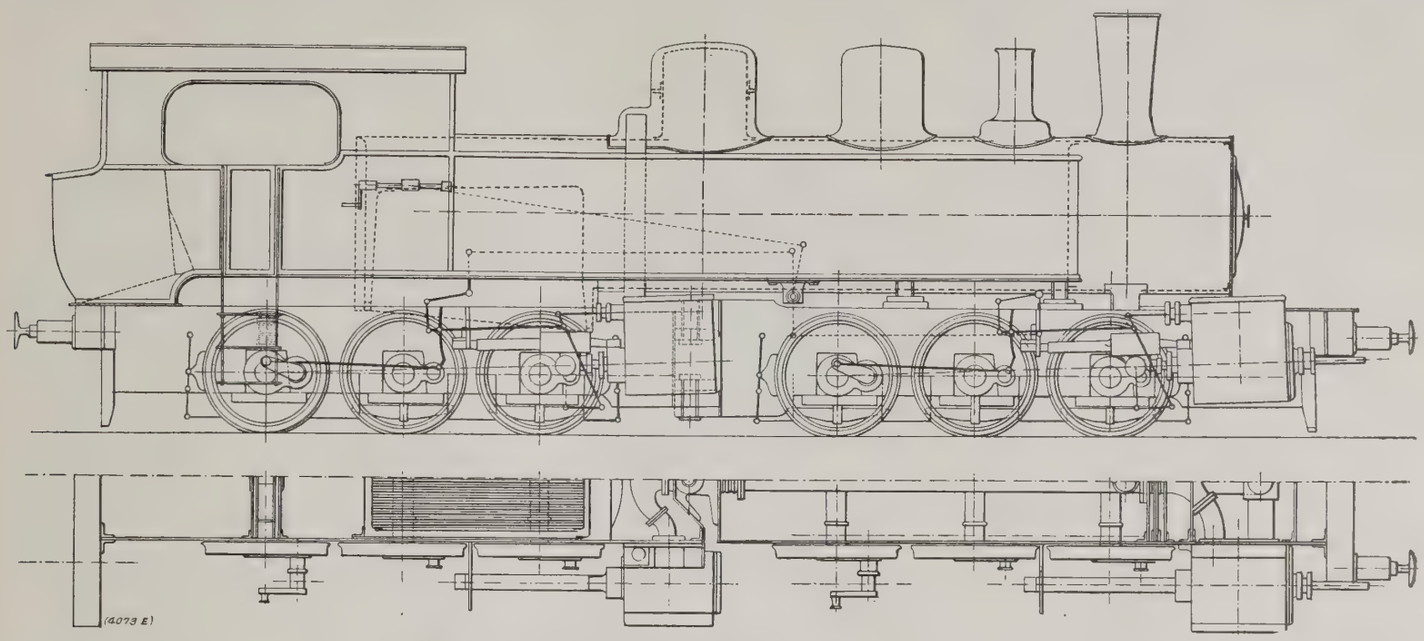

FIG. 5. LOCOMOTIVE FOR THE ST. GOTHARD RAILWAY, 1889.

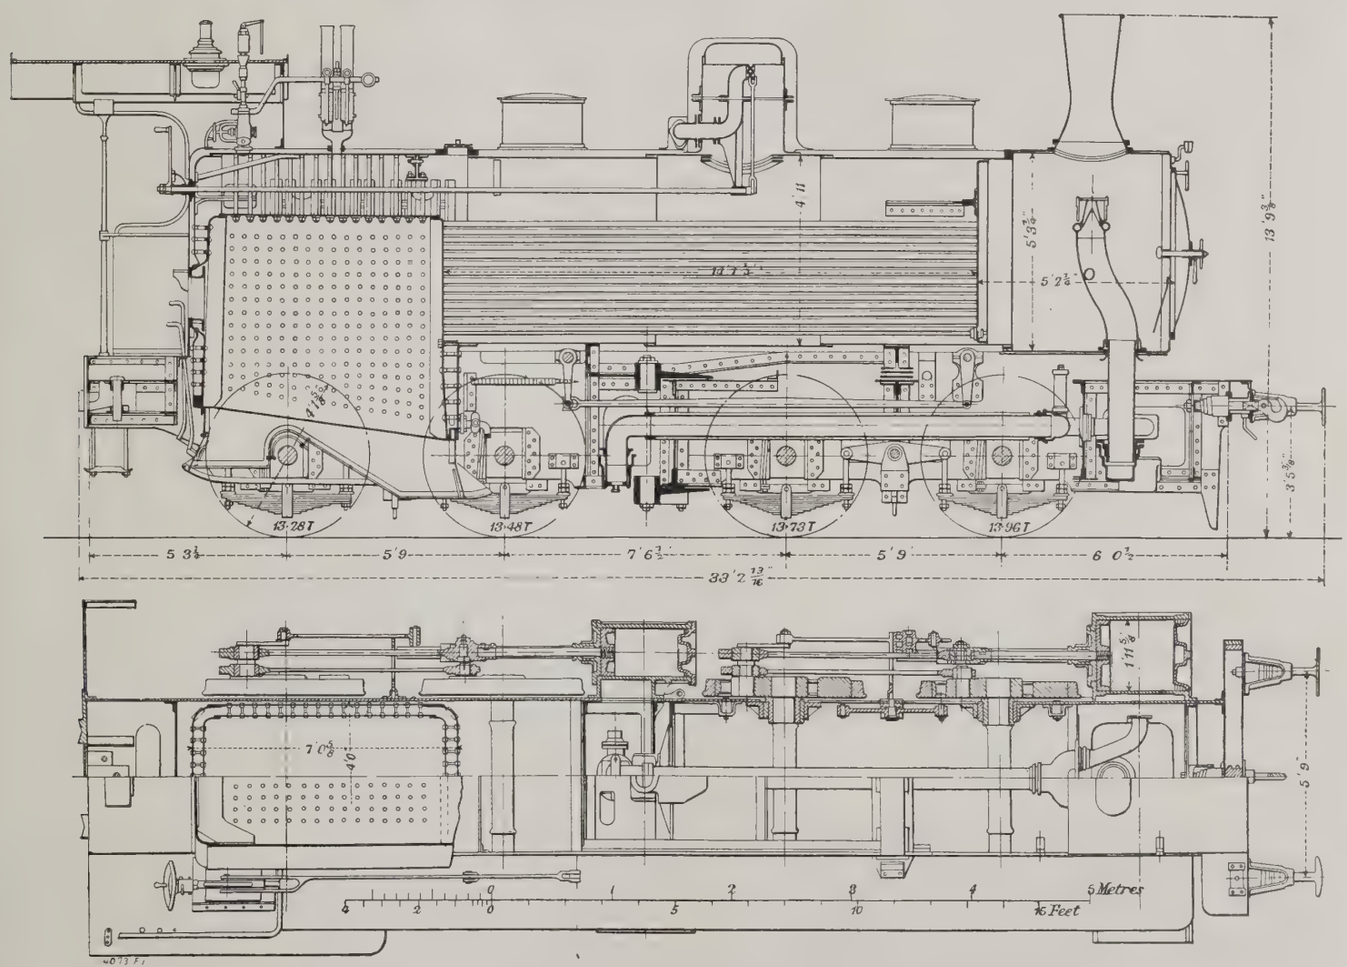

FIG. 6. LOCOMOTIVE FOR THE PRUSSIAN STATE RAILWAY; 56 TONS, 1894.

works, one of those small engines, and of explaining its mechanism to a number of English engineers who had been invited over by M. Paul Decauville. Mr. John A. F. Aspinall was at the head of the party.

As far back as 1888 the system had been applied (see Fig. 4) to tank locomotives with four axles, weighing 24 tons, running on the 1-metre (3 ft. 3.4 in.) gauge on one of the departmental railways in France, and in 1889 the "Maffei" firm of Munich constructed four engines

In 1894, engines on four axles and separate tender, weighing 56 tons, were built for the railways of the Prussian State, Figs. 6 and 7, on the present and following pages. As can be seen, the essential features do not differ materially from those of the first engine of 1887. Many similar engines were built for various German railways and for the Hungarian railways.

In 1895 six-axle engines with separate tender were built by Messrs. Borsig, of Berlin, and later by the Pontiloff firm, at St. Petersburg, for the 3-ft. 6-in. gauge of 850 km. (528 miles), from Vologda to Archangel, Fig. 8, page 54. It is interesting to note that it was not for flexibility that the system was adopted, since curves were not less than 350 m. (1148.3 ft.) radius, but it was for the light weight of rails, 18.5 kg. per metre (37.2 lb. per yard). This meant that a large number of axles must be coupled together, so as to obtain the required tractive power.

In 1898 another Russian line—the Moscow-Kazan line—had engines built on six axles, weighing 79 tons. One of these engines was exhibited at Vincennes at the time of the Universal Exhibition of 1900. A great number of these have been built, and superheated steam has been applied to the most recent engines. The director of that important company, Mr. Noltein, said at the Railway

Congress at Berne in 1910 that the Mallet locomotive is better than any other when it is desired to drive an engine of considerable weight over light rails. Under such circumstances it cannot be replaced by any other type with parallel axles.

The example given by the Moscow-Kazan Railway was soon followed by the Trans-Siberian Railway, to which the system was particularly suitable, given the lightness of the track: 24 kg. per metre (48 lb. per yard) rails. Two type-models of these engines, one for passenger trains with four driving axles and a carrying axle in front, weighing 56 tons in running order, and the other for goods trains with six driving axles, weighing 81 tons, were built with the intention of using them as patterns. These engines proved of great value during the Russo-Japanese War.

Large tank-engines on six axles were built in 1902 by Borsig, of Berlin, for the coal traffic on the Chemin de Fer Central d'Aragon. Gauge 1.676 m. (5 ft. 6 in.). These locomotives weighed 108 tons in working order, and were the heaviest built at the time, except in the United States. This company uses many engines of the same type but with separate tenders, weighing only 72 tons. Some of them, only recently built, by Henschel, at Cassel, are provided with Schmidt superheaters. As will be seen in Fig. 9, superheated steam comes from the smoke-box to the rear cylinders through two pipes placed outside the boiler. One can see how easily superheated steam may be applied to this type of engine where its use is as simple as on ordinary engines.

In conclusion, the author refers to the engines with six axles coupled with separate tenders, built in 1908, for the Chinese line from Pekin to Kalgan, by the North British Locomotive Company of Glasgow, which are the first engines of this type built in Great Britain. They weigh 98 tons, and pull trains on long 30 per cent. gradients, round curves of 152 m. (499 ft.) minimum radius. The author is glad to say that when he was revising this paper he learnt that the firm of Maffei, in Munich, the builders of the first normal-gauge Mallet engine, had recently constructed a huge tank-engine of the same type, with eight axles coupled in two groups. The engine weighs 122.5 tons in running order, and is, of course, the heaviest locomotive in the world, the United States excepted.

Table I., annexed, shows the principal dimensions of a few engines for narrow gauge, and Table II., page 55, gives those for wide gauge. The first engine of this type was built in 1887, as pointed out. In 1892 there were 110 of them in existence, and over 400 early in 1900. Since then the number has increased rapidly, and at present reaches about 2500. They are to be seen in about fifty countries distributed all over the world, and belong to about 150 different railway companies or administrations, some owning but a few, whereas others have from 50 to 350. It was in 1904, however, that the type made unexpected strides onwards. This was due to the following circumstances:—

There was then in the United States a very pronounced tendency towards reducing the cost of transport of goods by means of very heavy trains, so that powerful engines were required. The power of an engine is limited by the space between extreme axles and the weight which the wheels carry to the rails. Moreover, the following was unsatisfactory:—On many sections the track was very severe so far as grades and curves went. In 1902 the biggest American engine was an engine with five axles coupled and two carrying axles, weighing 120 tons, of which 106 tons was adhesive weight. It could give a tractive force of 28 tons. This engine belonged to the Atchison, Topeka and Santa Fé Railway, and was a compound tandem engine. For higher tractive forces three engines had occasionally to be coupled to one train. This was a costly, ungainly, and sometimes even a dangerous solution to the problem. The author had long come to the conclusion that the States, with their wider loading-gauge, their heavy weights per axle, and their method of coupling which made provision for an enormous tractive force, was just the ideal ground for the application of his system. He had entered into communication with an American firm, but without success. At last, in 1903, the American Locomotive Company constructed for the Baltimore-Ohio Railway a Mallet engine with six axles, weighing 152 tons (running order)—*i.e.*, 25.3 tons per axle—which was exhibited at St. Louis in 1904 (see Fig. 10). This engine was greatly criticised, and several engineers agreed to look upon it as a model—which would probably remain unique—of a monstrous locomotive, difficult to handle for everyday traffic, and being serviceable only as a pusher on very broken lines, or on lines of determined gradients. There was also a doubt as to the way the coupling of the two trucks and the movable tubing would behave in practice. When the engine started to run, after the Exhibition, it was found that those criticisms were based on nothing serious, and that the hopes of its success had not been exaggerated.

Two years later, in 1906, the Baldwin firm, which had already built a few similar engines for the narrow gauge of Porto Rico, delivered five engines to the Great Northern Railway, U.S.A., with six driving axles and two carrying ones—one in front, the other behind—weighing 162,000 kg. (159.4 tons), of which 144,000 kg. (141.7 tons) was adhesive weight (Fig. 11). These engines, like the first one, played the *rôle* of "pushers," but the excellent results they gave prompted the company to use them for road service—that is, for pulling goods trains—and twenty-five like engines, weighing 130,000 kg. (128 tons), of which 113,000 kg. (111.2 tons) was adhesive weight, were ordered. These engines pulled 1300 tons at a speed of 16 km. (9.9 miles) per hour on a gradient as high as 1 per cent., on which the consolidation engines only took 1000 tons, using the same amount of coal; this meant a saving of 30 per cent. In 1907 a further step was taken in increasing the number of driving-axles when the Erie Railway ordered three locomotives on eight axles, weighing 185,500 kg. (173.7 tons), entirely for adherence. These engines were intended to haul trains of 3000 tons over the 12-km. (7.5 miles) section on a gradient of 13 per cent. between Susquehanna and Golf Summit. This was done successfully, and a considerable saving in staff, coal, and time was the result. From that time many American lines started using this new type.

Another interesting fact to consider was that the introduction of the new engines, which were very powerful, caused the ordinary engines to be discarded. Mr. George H. Emerson, of the Great Northern Railway, conceived the idea of combining his consolidation engines, two by

two, and turning them into Mallet engines with the introduction of new boilers. This transformation gave good results, and locomotives of the Prairie type were treated in the same way. But the most remarkable transformation was that carried out by the Atchison, Topeka and Santa Fé Railway using locomotives with ten wheels coupled, already referred to.

In 1902 they were the largest engines in the United States. The frames were utilised for the rear portion of the new engines, and the original low-pressure cylinders of 0.813 m. (2 ft. 8.01 in.) diameter were fitted with inside liners so as to reduce the diameter to 0.711 m. (2 ft. 4 in.) and transform them into high-pressure cylinders. A front truck was added, carrying the low-pressure cylinders of 0.965 m. (3 ft. 2 in.) diameter, and a new boiler

was fixed containing, owing to its length, a superheater, a steam re-heater going from one group of cylinders to the other, and a re-heater for the feed-water. These newly-transformed engines scaled the enormous weight of 227,000 kg. (223 4 tons), of which 200,000 kg. (196.9 tons) was adhesive weight, distributed over ten axles.

The company has, besides, constructed others on the same model, heavier still, weighing 280,000 kg. (275.6 tons), of which 250,000 kg. (246 tons) is adhesive weight, and which give them, when working compound, a tractive force of 50,000 kg. (50 tons) at tread of wheels.

Table III., page 56, gives the main dimensions of some of these engines. It will be seen that for a few the diameter of low-pressure cylinders is equal to, if not greater than, that of the boilers of sixty years ago.

There are actually on American railways the following types of Mallet engines:—2-4-4-2, 4-4-6-2, 0-6-6-2, 2-6-6-2, 2-6-8-0, 0-8-8-0, 2-8-8-0, 2-8-8-2, 2-10-10-2. These engines are to be seen at the present day on some forty lines in the United States. They are used for various purposes, either on easy lines for very heavy trains or

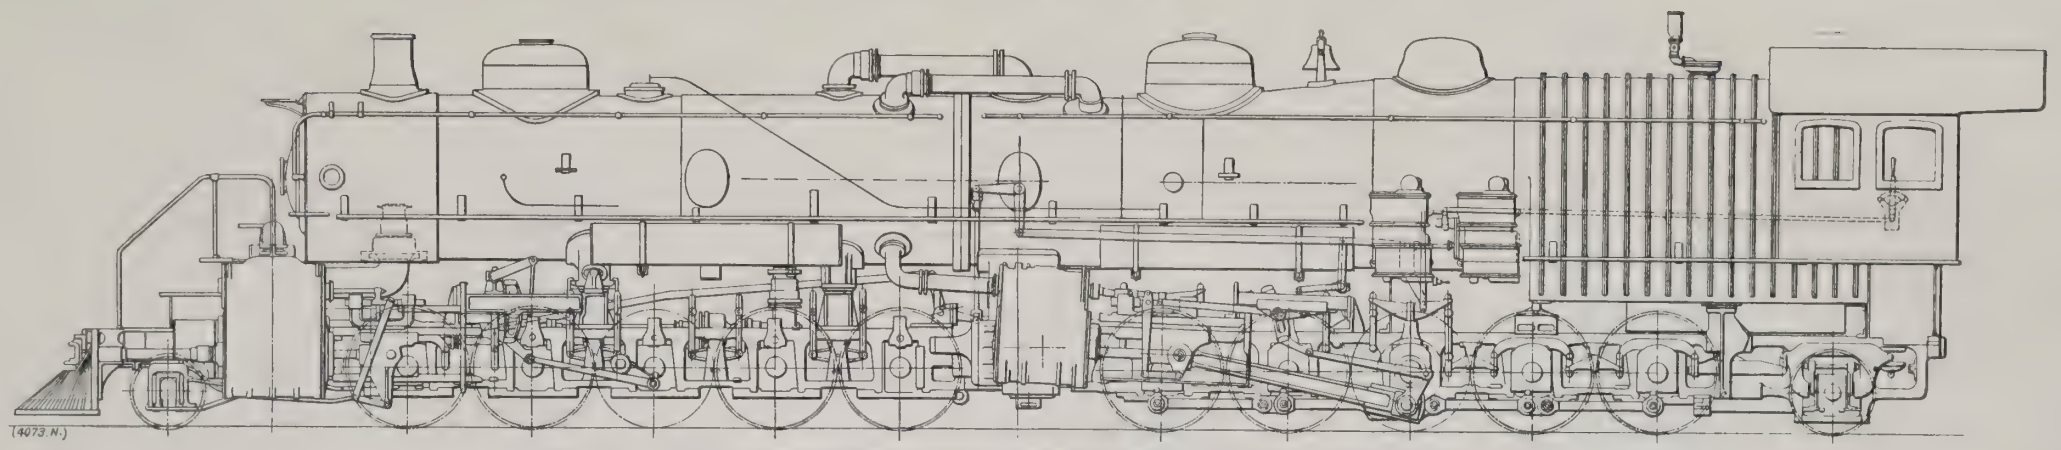

FIG. 13. 2-10-10 2 LOCOMOTIVE FOR THE ATCHISON, TOPEKA, AND SANTE FÉ RAILWAY, 1911.

with less loads on severe gradients. According to American engineers, the adoption of this system is justified by the following advantages :—

1. Distribution of adhesive weight over a great number of coupled axles.
2. Diminution of weight on the wheels, reducing the deterioration of track and bridges.
3. Considerable distance between extreme axles and reduced distance between parallel axles.
4. Great flexibility of the engine, reducing the wear of rails and flange.
5. Advantages arising from the use of double expansion and superheated steam where economy is concerned.
6. Division of the mechanism into two sets.
7. Small relative weight of the pieces of the mechanism and decrease in repairs.
8. Reduction in the repairs of the boiler as compared to those of the engine, owing to there being only one boiler for two engines.
9. Ease and simplicity of driving.

To these advantages it may be added that the use of double expansion reduces the slipping of the wheels considerably. Articulated locomotives, with double high-pressure cylinders independent of one another, often give rise to difficulties in running, due to the fact that when they are working at full pressure on an incline it is nearly impossible to make both cylinders give the same hauling power, and either the one or the other starts to slip. Trains frequently stop on severe gradients for that reason. Such is not the case with articulated compound locomotives on account of the reliability of the two sets of cylinders working on the same steam. If the high-pressure group start to slip, the cylinders of that group exhaust their steam in the receiver quicker than the low-pressure cylinders can use it, and the pressure at the receiver as it goes up stops the slipping. In the same way, if the wheels of the front group start to slip, the low-pressure cylinders discharge steam quicker than the high-pressure cylinders can feed them, and the pressure goes down at the receiver, so that the wheels cease slipping. If slipping take place in both groups at the same time, action can be taken accordingly as with ordinary engines.

The arrangement of articulated frames used by the author has been criticised. It means this advantage, however, as was pointed out in a pamphlet published by the Baldwin firm ; so long as the effort exercised by the driving connecting-rod on the crank-pin is not at a dead end, the pressure of steam tends to push the bottom of the cylinder and the frame in opposite directions. In articulated engines this is according to an arc of a circle described with the axis of articulation as centre. If the pistons on both sides worked together the two actions would balance one another, but the crank-pins are placed at 90 deg., so that during one turn of the wheel there is a point when the pistons are moving in opposite directions, and twice in every revolution they are tending to turn their separate frames, first one way then another. All engines have a certain amount of play, either between the rails and the flanges of the wheels, or in themselves, so that movement may take place laterally for an amount equal to the sum of these oscillations. But before this displacement is reached it is first of all counteracted by inertia, then by friction of the flanges against the rails, and by more friction like that of the journals in the axle-boxes, &c. The sum of these resistances multiplied by the radii x and y, Fig. 14, at the end of which the resistance takes place, represents the resistance of the engine against transverse displacement. This resistance is greater for the Mallet than for the Fairlie engine, on account of the greater length of the lever-arm. In the two types the reaction on the crank-pin is tangential to an arc of a circle having for its radius c the distance of the axis of articulation from the axis of the cylinder and the moment of rotation is the product of the reaction by this radius. From which it follows that the Mallet engine is more stable than the Fairlie ; for with equal loads on the driving-wheels and the same distance between axles, it opposes a greater moment of resistance to the displacing factors.

Lateral stability is a very important item, for if the moment is insufficient the engine will continually oscillate and bring about a rapid wear of the flanges and excessive play. This is opposed to safety, and in any case means very costly upkeep. A few engines of this type have been constructed with cylinders of equal capacity (all working at high pressure). The author does not advocate this scheme, in which one is deprived of the advantages to be realised by the adoption of double expansion both for simplification of piping and reduction in slipping. This system is only justified in the case of a loading gauge which does not allow the adoption of low-pressure cylinders of convenient diameter.

The author believes he could not do better than conclude with an extract from a paper read at the Franklin Institute on January 16, 1910, by Mr. Grafton Greenough :—

"We find that wherever continuous heavy road service or heavy pushing service is required, the Mallet compound articulated locomotive has more than done what was expected of it. We also find it, because of the articulated features, adapted to lighter work where rigid base wheel engines are not practicable. In all heavy service, of a nature which enables an engine to work a considerable portion of its time to anything like maximum efficiency, we find that, in addition to being more effective than other types of engines, the Mallet locomotive is by far the most economical design of locomotive yet devised. Without doubt its advent has eliminated the necessity—for a time at least—of widening the gauge of our railroads, and has, in many instances, postponed the laying of additional tracks, because of the reduction in the number of train movements it makes possible. Furthermore the introduction of the Mallet type of locomotive has justified the retention of steam locomotives as motive power on economical grounds alone, where, in a number of instances, electricity generated by water-power bids fair to invade.

"That the solution—for a time at least—of the apparently insurmountable difficulties attending the hauling of heavier trains, has been obtained with practically no change in roadways, is due primarily to the common-sense design of locomotive, developed by Mr. Anatole Mallet, seconded by the untiring energy and perseverance of the railroads officials, who in conjunction with the builders of locomotives had the temerity to give these engines a fair trial, and so mould their particular features to comply with modern railroad conditions that their efficiency is no longer an experiment, but a positive accomplishment."

The author deems it his duty to bring forward the above opinion of American engineers to the notice of European railway engineers and locomotive builders (the latter numbering about thirty), to whose initiative and ability the results which have been set forth in this paper are greatly due.

ADVERTISEMENT RATES.

The charge for advertisements is three shillings for the first four lines or under, and eightpence for each additional line. The line averages seven words. Payment must accompany all orders for single advertisements, otherwise their insertion cannot be guaranteed. Terms for displayed advertisements on the wrapper and on the inside pages may be obtained on application. The pages are 12 in. deep and 9 in. wide, divisible into four columns of 2¼ in. in width. Serial advertisements will be inserted with all practicable regularity, but absolute regularity cannot be guaranteed.

Advertisements intended for insertion in the current week's issue must be delivered not later than 5 p.m. on Thursday. In consequence of the necessity for going to press early with a portion of the edition, alterations for standing advertisements should be received not later than 1 p.m. on Tuesday in each week.

SUBSCRIPTIONS, HOME AND FOREIGN.

"ENGINEERING" can be supplied direct from the Publisher post free, for twelve months, at the following rates, payable in advance:—

For the United Kingdom	£1	9	2
For Canada—			
Thin paper copies	£1	11	6 ($7.65)
Thick ,,	£1	16	0 ($8.75)
For all other places abroad—			
Thin paper copies	£1	16	0
Thick ,,	£2	0	6

When foreign subscriptions are sent by Post-Office orders, advice should be sent to the Publisher.

Foreign and Colonial subscribers receiving incomplete copies through newsagents are requested to communicate the fact to the Publisher, together with the agent's name and address.

All accounts are payable to "ENGINEERING," LIMITED. Cheques should be crossed "Union of London and Smith's Bank, Limited, Charing Cross Branch." Post-Office Orders should be made payable at Bedford-street, Strand, W.C.

Offices for Publication and Advertisements, 35 and 36, Bedford-street, Strand, London, W.C.

We desire to call the attention of our readers to the fact that the above is our SOLE ADDRESS, and that no connection exists between this Journal and any other publications bearing somewhat similar titles.

ENGINEERING.

FRIDAY, JULY 10, 1914.

PROTECTION AGAINST FIRE ON BOARD SHIP.

IT is a remarkable fact that, notwithstanding the great developments that have taken place in every detail in the design of merchant steamships, little or no progress has been made towards the effectual protection of the vessel against fire excepting, perhaps, in the direction of improvements in the pumps and in the distribution of pressure water from them. In the case of warships it has for some years been realised that one of the dangers to be met in naval engagements is fire, due to the action of the explosive contents of the shells which may penetrate into the interior of the ship, and progress has been made in the direction of ensuring that the whole of the interior fittings shall be of a non-combustible material. It cannot be said that there has been great loss in decorative effect, although in this matter the warship is in an entirely different position from the modern liner. No attempt has been made, even in warships, to introduce furniture made of metal which will resist fire, the theory being that, before an engagement is entered upon, all wooden furniture, as well as all portable combustible material, &c., will be jettisoned.

In the merchant service there is not the same risk of fire as with warships in action, but statistics show that during the past eight or ten years there have been annual averages of over 300 outbreaks of fire on board ship, either in port or at sea, while the number of ships completely destroyed by fire averages over twenty per annum. This may not seem a large figure when one remembers that on the register of the United Kingdom alone there are nearly 21,000 ships, and that probably throughout the world there are 50,000 ships continuously in service. At the same time the possible loss of life, and the probable destruction of property consequent on fire, should encourage careful consideration of all possible methods not only of preventing an outbreak, but of quickly and effectually arresting it in the initial stages. Undoubtedly in the case of passenger - ships the publication of the fact that something had been done towards this end would have an effect on the bookings corresponding to that resulting from the evidence given of the possession of lifeboats for all. In the new Hamburg-Amerika liners Imperator and Vaterland Grinnell sprinklers have been introduced, and this fact alone justifies a consideration of the effectiveness of this method of combating fire on board a ship.

The extent to which such automatic sprinklers are used in mills, factories, warehouses, stores, halls, theatres, &c., and the disposition of fire insurance companies to grant rebate on the premiums of fire insurance policies when sprinklers are fitted, is evidence in favour of the efficacy of the same system on board ship. The conditions, particularly in the passenger quarters, are most favourable, because here the space is so minutely divided up by iron decks, transverse bulkheads, and even by cabin and alleyway walls, that the initial outbreak of a fire is confined within a limited area, and were automatic sprinklers immediately brought into action, the fire would the more likely be quenched. As to the freezing of the water in the pipes—an argument sometimes used against the system—the dry-pipe system has proved an effective preventive. In this system, so-called pressure tanks are provided, containing sufficient water for a primary supply, and this water is held in check by a specially designed differential valve, having water pressure on one side and air pressure on the other. When the rise in temperature, due to the starting of a fire, melts the solder of the sprinkler, the opening of the head liberates the air, reducing the pressure, and the valve is opened by the water-pressure above it exceeding the air-pressure under it. Thus the water flows freely through the pipes and out of the open heads. The inspection department of the Associated Factory Mutual Fire Insurance Companies of America, which has been responsible for the fitting of sprinklers to quite a number of American ships, including coasting, river and lake passenger-steamers, estimates that with any sprinkler system on board ship the heads would be spaced about 10 ft. apart, each protecting 100 sq ft., and that the cost of such an installation would average about 16s. per head, excluding the cost of the pumps. In land practice the cost is only about 12s. per head, but the ship installation would probably cost more.

The treatment of holds where cargo is carried involves a special application, particularly where the cargo is of a material with a tendency to spontaneous combustion. It would be difficult for sprinklers, and even for a hose, to subdue a fire of this nature, although it might postpone serious consequences sufficiently long to enable the ship to reach port. The authority already quoted has adopted a system of introducing carbon dioxide into warehouse compartments, which are analogous to ships' holds. The carbon dioxide is purchasable in a form liquefied under pressure and contained in drums. The liquid gas is passed through pipes and exudes through openings at the top of the warehouse or hold, its specific gravity causing it to sink, and thus to penetrate the interstices of the cargo during its descent; the result is that combustion is rendered impossible, and the fire is either held in check or completely extinguished, the gas ultimately being driven out or sucked out by fans. The difficulty is that the carbon dioxide, though not explosive or directly dangerous to life, tends towards asphyxiation. But a man can live for a limited time in an atmosphere containing 10 to 15 per cent. of it, and it is computed that from 30 to 40 per cent. is sufficient to extinguish a fire. It is not dangerous to merchandise, and the quantity required is about a 50-lb. cylinder per 1000 cub. ft. of air. Sulphur dioxide has been used, but the authority quoted found it objectionable, as men could not live in an atmosphere containing any appreciable amount of the gas; moreover, it is injurious to certain kinds of merchandise.

In addition to this means of extinguishing an outbreak consideration should be had, in merchantship practice, to the adoption to a larger extent of metal in preference to wood. It is true that so-called fire-resisting paints are largely used, but there is doubt of the efficacy of the great majority of such paints. In preference to wood a light steel might be used, especially if lined with non-combustible insulating material in order to secure a more equable temperature within the cabins in climates where extreme weather conditions prevail. In recent years there has been considerable development in the simulation of wood-carving and decorative effect generally in the production of metal furniture; but, even so, we are a long way from achieving the artistic effects which can be got from wood. In the modern liner, however, plaster-of-paris and other such materials are being more and more relied upon for decorative purposes. Indeed, in some of the newer ships it is difficult to grasp the fact that one is not in a room on shore, because of the treatment of the ceiling and walls. If this plaster-of-paris work proves to be lasting, a way is opened up for the use of light-steel partition walls with insulating materials in preference, or in addition, to the plaster-of-paris.

The question is largely one of expense. The substitution of steel and plaster for wooden decks, cabins, &c., in medium and large passenger vessels would involve an increase in expenditure up to 10 per cent. of the cost of the entire ship, excluding even the extra cost of steel furniture, if such were used. This is a serious addition to the price of a ship, and when to it there has to be added the cost of automatic sprinklers, it will be obvious that the shipowner will have to consider whether the advantage accruing from increase in favour with the public, and consequently more consistently full passenger lists, with the addition of a reduction of insurance rates, can compensate him for the expenditure. There can be no question that a ship so treated would be more immune from the risks of fire than an ordinary vessel depending only upon the fire-pumps; but the final answer is, we fear, one concerned with the relation of safety, and its influence on earning power, to the cost involved. The matter is one that will be decided finally by the public. If they make it clear that they are ready to pay for increased security, then it is certain to be attained, for manufacturers will vie with one another in discovering new materials, and in devising novel methods of treating old ones to render them durable and artistic. Shipowners have shown such

readiness to add to the comfort and speed of their vessels that there is no doubt they will meet all demands that are commercially practicable.

EXPLOSIONS IN ELECTRIC MAINS.

The unanimous report of the Departmental Committee on Electric Mains Explosions, just published,* should tend to allay the apprehension which has arisen in many quarters as to possible danger from the use of bituminous or pitchy compounds for the insulation and protection of buried electric mains. Explosions have occurred chiefly in separate mains carrying continuous current, insulated with vulcanised bitumen, either drawn into bitumen conduits or laid solid in troughs filled with bitumen. But the Committee does not find any sufficient grounds for recommending the Board to prohibit this system of laying, as it is probable that accidents which have occurred through it could also be partly assigned to other contributory causes.

The particular points requiring attention are: the method of making bends, which should have easy turns; the proper shape of the troughs, which should be filled in after the straights have set; the means for taking off the services, which should be armoured cables and be gas-proof from main to house; and the danger of covering with an impervious pavement. The following features are exonerated from blame as the cause of serious explosions :—Alternate-current supply, concentric cables, three-core cables, lead-covered paper-insulated cables, cables laid solid in pitch compound. It is noted, however, that bitumen has been so much more extensively used than pitch compound that a proper comparison between the two cannot be made. With regard to troughing, the Committee finds no superiority in iron or stoneware over wood, except where the soil is proved to be unsuitable for wood. It is recommended that separate mains be laid, each in a separate trough, with at least 2 in. of tightly-packed earth or sand between.

Considering the hundreds of miles of mains laid solid in bitumen under streets, the actual number of accidents arising from them is relatively very small, some two deaths only being caused, and some sixteen or seventeen persons injured by them, during the last eleven years. The immediate cause of the explosion is the ignition of gases evolved from volatilisation or destructive distillation of the bitumen insulation and packing round a fault in the main. It is shown that bitumen deteriorates from (1) contact with coal-gas; (2) injury inflicted after laying, or original defect, on a positive main, permitting a small leak to earth, causing corrosion and ultimate failure of the conductor; (3) an earth on a negative main, decomposing the insulating material, and producing a leak from positive to negative, ending in short circuit. In such cases an arc forms, which may either be quenched by the bitumen it melts, or may persist, decomposing the insulating vulcanised bitumen and also the packing. These are circumstances of greatest danger, for at a high temperature large volumes of very inflammable gases are given off. The gases take the line of least resistance, possibly into a house or manhole. It will easily be seen that the most favourable conditions concur with several cables at different pressures in the same trough.

It is admitted that bitumen and pitch compounds offer the only practical alternatives as filling material for cable-troughs. The bitumen should liquefy freely between 250 deg. and 350 deg. Fahr., weld readily to adjacent layers, adhere to cables and bridges, and retain such viscosity in the ground as to allow it to bend slowly and to reunite if fractured. It should not be heated above 400 deg. Fahr. The alternative pitch should be coal-tar pitch, softened with pitch or creosote oil. In some cases whinstone dust is afterwards added to strengthen the mixture. Two such mixtures are quoted—namely, (1) 3 tons pitch, 2 tons stone-dust to 10 gals. pitch or creosote oil, and (2) 10 cwt. pitch, 10 cwt. limestone dust to 10 gals. tar oil. This is cheaper than bitumen, runs at 260 deg. Fahr., and has specific heat 0.5, while that of bitumen is 0.8. Thus the pitch compound causes much less heating of the cable when filling. The pitch compound also adheres well to unglazed stoneware bridges, and is not affected by coal-gas or creosote.

Considerable attention was given by the Committee to the question of testing and localisation of faults. Vulcanised-bitumen-insulated cables are the most difficult in this respect. It appears that the allowable leak depends on the size of the undertaking, but varies greatly. In one town with a peak load of 35,000 amperes a leak of 10 amperes is taken to indicate a fault, while in another the normal leak is 20 amperes on a peak load of 8000 amperes. No suggestion is made for a general standard, but evidence was taken on the advisability of dividing large networks into districts interconnected by fuses or circuit-breakers. The most workable unit would seem to be a district taking about 600 to 800 amperes.

Not the least interesting part of the report is the special report from Dr. R. V. Wheeler, of the Home Office Experimental Station, Eskmeals, to decide the following points :—

1. There is no tendency to spontaneous combustion or self-heat on the part of the finely-divided carbon from gaseous hydrocarbons decomposed at a high temperature.

2. Gas from bitumen at 1000 deg. Cent. is explosive when present in the air between the limits of 5.4 to 20.5 per cent., and gas from pitch compound between 10.7 and 47.5 per cent. Up to this temperature, therefore, the gases from pitch compound are the more dangerous, as remaining explosive within a greater range of mixture, but if the gases are "cracked" or broken up by passing over a very hot surface, this difference largely disappears, the limits of inflammability of both being widened, but more in the case of bitumen gases than pitch gases.

3. There is very little to choose between the bitumen and the pitch compound in the matter of the volume of inflammable gases evolved up to 1000 deg. Cent., Callender bitumen giving 3.1, Glasgow pitch 2.5, and pitch compound 2.8 cub. ft. per lb., reduced to normal temperature and pressure, but, considering the wider limits of inflammability of pitch gases, the latter would be more dangerous, subject to the remark on cracking in the last paragraph.

The report goes on to give the nature of the gases evolved, in which hydrogen and carbon monoxide largely predominate, especially when cracked. It also gives details of the experiments made and apparatus used, and will well repay study on the part of those who are concerned with the behaviour of volatile oils and solids, as well as of those who are directly interested in the question of electric mains protection.

* Report of the Committee of Inquiry appointed by the President of the Board of Trade. London: Wyman and Sons, Limited. [Price 3d.]

FACTORY BUILDINGS.

FACTORY buildings are of all kinds. In certain cases the adoption of cheap corrugated iron sheds may be fully justified by certain special conditions, whilst in other cases the erection of more elaborate and more expensive structures may be truly economical, the higher first cost being more than counterbalanced by a much lower expenditure in maintenance. Until recent years such permanent buildings were almost always of brick and steel, but of late ferro-concrete has met with much favour, and its advocates claim that under normal conditions a ferro-concrete building is considerably cheaper than one of brick and steel, even if the latter is provided with a roof of corrugated iron, which, of course, involves a considerable expenditure in maintenance. In one case, recently referred to in a paper before the Concrete Institute, it was stated that competitive tenders showed that a factory constructed throughout of ferro concrete (roof included) would cost 12 per cent less than an alternative design in brick and steel, with a roof of corrugated iron. The local conditions were in no way specially favourable to the ferro-concrete, the aggregate having to be brought 25 to 30 miles by rail. The building in question was constructed throughout of ferro concrete, but generally it is cheaper to execute the panels in brick, the reinforced material being then reserved for the columns, beams, floors and roof. Such a structure is, of course, remarkably permanent, since even the indifferent concrete-making materials which were available to the Roman architect and engineer have shown an extraordinary endurance. There is, of course, a popular misconception that ancient cements were incomparably superior to our own, a belief mainly attributable to the characteristic ignorance of literary men and antiquaries. Claims of this kind are, in fact, always being made, amongst the latest being one that in domestic sanitation the Minoan age was fully abreast of the best modern practice. In all probability the archæologists responsible for this opinion could not define the difference between a wash-down and a wash-out closet. Nevertheless, their views get into the public Press, and thus become almost ineradicable, owing to an apparently inexpugnable desire on the part of certain popular writers to belittle the achievements of modern applied science.

Many engineers prefer to use steel rather than ferro-concrete stanchions, owing to the ease with which attachments can be made to them at any future time. Mr. P. M. Fraser, the author of the paper referred to, claims that in this respect the advantage lies with ferro-concrete, since an inch-hole, for example, drilled into a ferro-concrete beam or column, reduces in general the gross section by a smaller percentage. This may be quite true, but whilst, with a reasonable exercise of judgment, an attachment to steel-work may be made almost anywhere without serious risk, there is always the possibility that in drilling ferro-concrete the drill may encounter some of the concealed reinforcement. It is of importance to allow for a very ample factor of safety in designing columns, whatever be the material used. In erecting a new factory building it is often quite impossible to foretell with certainty what loads the columns may be required to carry in future years. The same consideration also applies to the design of the floor, and we have known instances, in printing works in particular, in which weights have been piled on galleries very much in excess of what had been anticipated by the designer. In this respect steel would appear to have a considerable advantage over its rival, since, if need be, a steel beam can be strengthened by additional plates, whilst a corresponding operation would hardly prove satisfactory with ferro-concrete.

It is sometimes claimed that ferro-concrete is specially suitable for engine foundations, but the conditions in which this may become necessary must be somewhat rare. What is generally required in such foundations is weight rather than great strength, and this is so commonly recognised that there is at times difficulty in preventing some contractors omitting from such foundations much of the cement specified, their view being apparently that anything that will stick together is good enough for an engine foundation.

Incidentally in his paper Mr. Fraser made some criticisms of English methods which are, we think, far from being justifiable by experience. The latter shows that slightly inconvenient buildings are not always as heavy a handicap as Mr. Fraser contends. For certain trades, particularly those in which articles are built in large quantities to stock, only extremely low annual charges may make feasible competition with firms more conveniently housed. Nevertheless, as is well known, firms with old machinery and old factories are by no means always unsuccessful, the reason being that the cost both of buildings and plant has been completely written off many years ago, and hence somewhat higher working expenses do not necessarily preclude effective competition. Where a varied class of work is done, hardly two jobs being alike, conditions are still more equal, since the newer factory cannot then have as effective an organisation as it may have in more specialised fields. Other things being equal, a well-arranged building is, of course, an enormous asset to the manufacturer. Many small firms have, however, to put up with what they can afford rather than with what they would prefer, and they manage to make profits in spite of certain inconveniences.

THE JOINT MEETING OF NAVAL ARCHITECTS AND ENGINEERS AT NEWCASTLE.

THE joint summer meeting of the Institution of Naval Architects, the Institution of Engineers and Shipbuilders of Scotland, and the North-East Coast Institution of Engineers and Shipbuilders, which is being held at Newcastle-on-Tyne, opened auspiciously on the 7th inst., when the various institutions were welcomed by the Right Hon. the Earl of Durham, K.G., as the chairman of the local reception committee. The official welcome took place in the King's Hall of the Armstrong College, and in addition to the Earl of Durham, the Right

Hon. the Lord Mayor of Newcastle-upon-Tyne, and Sir Charles Parsons, as President of the North-East Coast Institution of Engineers and Shipbuilders, delivered brief addresses of welcome. There was an excellent attendance, although the Marquis of Bristol, in replying for the Institution of Naval Architects, pointed out that many who would have attended from Scotland were prevented from being present by the visit of His Majesty the King to Glasgow. It was hoped, however, that most of these gentlemen would be able to come to Newcastle for the closing days of the meeting.

The Chairman announced that he had just received from Holyrood Palace a telegram sent by His Majesty the King, expressing his interest in their gathering. This telegram was as follows:—"The King is much interested in the meeting, now assembled at Newcastle, of the three Institutions representative of the shipbuilding and marine engineering of the Empire, and wishes it every success." The reading of the telegram was received with warm applause, as was also the proposal of Lord Durham that the grateful thanks of all present should be conveyed to the King for his gracious message.

Before dealing with the technical part of the proceedings, which is our proper province, we desire to express our sympathy with the Marquis of Bristol in the personal bereavement which prevented him taking other than a formal part in the meeting, and deprived the social features of the gathering of the presence of Lady Bristol.

BATTLESHIPS AND SUBMARINES.

The technical papers on Tuesday last, the first day of the meeting, were presented by members of the Institution of Naval Architects. The first, which was taken in the King's Hall before the whole of the assembled company, was by Professor Sir John H. Biles, and was entitled "On the Protection of Battleships against Submarine Attack." We reprint this paper in full on page 65 of our present issue. It was read by Sir John, who stated that it was really a stop-gap paper, prepared to take the place of one on the subdivision of ships, which was to have been read by Professor Welch, who had, however, been obliged to go to Canada in connection with the Empress of Ireland inquiry.

Lord Brassey opened the discussion. He said that as a veteran and old president he had been asked to do so. He thanked Sir John Biles for his most valuable paper, but did not feel competent to answer the four points which appeared at the end of it. It might be possible to build such ships as the paper proposed, but one thing which seemed clear to him was that it would not pay to put too many of our eggs in one basket. We might accept the inference that a given speed and armament were necessary, but that did not necessarily imply acceptance of a given size of ship. The same total armament might be distributed over a greater number of ships. An equal armament might cost more under these conditions, but the proposal could not necessarily be scouted on that score.

Mr. C. E. Ellis, the next speaker, said that Sir John Biles had hoped that Sir Andrew Noble would say a few words in connection with the questions of armour raised by the paper, but Sir Andrew had unfortunately been unable to attend, and had asked him to speak in his stead. A worse man could hardly have been chosen. Whatever knowledge might exist on the question of the resisting power of armour against torpedo attack did not reside with him or with any other armour-maker. No doubt the Admiralty had some knowledge in reference to the matter, but he had not. He was glad he had not. If he had, he might feel it necessary to give the meeting the benefit of his knowledge, and that would hardly have been permissible, as obviously any data on the subject must be based on Admiralty experiments.

All he would say was that any armour developed for protection against under-water attack might well be of somewhat different type from that at present used. It might be that a lighter protection would be sufficient. That was for the expert to decide. The history of armour showed that on the whole it had been capable of meeting the attacks of its enemies. It had fought the gun, and, he thought, on the whole, had fought it successfully. It had also given a good account of itself against torpedo attack on the water-line, and he thought it would prove capable of providing defence against this insidious attack below water. As a final point, he would say that in the last few years the armour-makers had found it necessary to provide armour of shapes which previously they could not manufacture. They had done this with success, and there was little doubt that in the future they would be able to furnish armour of any shape likely to be required.

Admiral Sir Reginald Custance, who continued the discussion, said there were a large number of questions raised by the author, and it was necessary he (the speaker) should confine himself to what he considered the gist of these questions. That was:—What was the war value of the Whitehead torpedo? In the first instance, it was necessary that one should not be misled by the results of peace practice. They were entirely different from those furnished by war. In the Russo-Japanese war there were four engagements in which torpedoes were employed. These were the first surprise attack outside Port Arthur, the first sortie of June 23, the second sortie of August 10, and the battle of Tsushima. In all, some two to three hundred torpedoes were fired, and of these about 5½ per cent. resulted in hits. Even so, many of these concerned ships at rest or moving very slowly, and only about 2 per cent. of the torpedoes fired at ships in motion reached their mark. This was a great falling off from the results of peace practice. It should further be noted that no ship sank immediately on being struck by one torpedo. The ships that foundered at once had been hit by three or four torpedoes, and had further been much damaged by gun-fire. These figures suggested that there was a very fair probability against a particular torpedo doing much damage.

What was the explanation of the low percentage of hits? At the time of the Russo-Japanese War a torpedo could travel at 50 ft. a second. Now they could travel at 75 ft. a second. When a torpedo was fired at a ship in motion it had to be aimed a considerable distance ahead of her; and as her speed and course were not known, great difficulty was introduced. Further uncertainty arose from the fact that one was not certain about the speed of his own torpedo; also it was necessary to fire it at the exact moment when the sights were on. This was not easy. Then questions of imperfect management crept in. The torpedo was set for short range, and fired for long range, and so on. Again, torpedoes might be erratic, and sometimes turned round and came back at the boat that had fired them. Not very often perhaps, but still it might be in 1 per cent. of cases. When all these difficulties came in, and had to be allowed for on a dark night under gun-fire, when the enemy was suddenly sighted, the wonder was that torpedoes ever hit their mark at all. Besides, all this went on at very close range—within 400 yards—when gun-fire became a very serious matter.

Errors in the course and speed of torpedoes also depended on the speed ratio. This was the ratio between the speed of the torpedo and the speed of the ship. From the point of view of this ratio, nothing must be taken off the speed of the ship. In the Russo-Japanese War the cruisers had a speed of about 17 knots, and the battleships a speed of from 13 to 8 knots, or even less. The speed ratios varied from $\frac{5}{3}$ to $\frac{4}{1}$. The ratio had not changed at the present day, as the increased speed of the torpedo had been offset by the increased speed of the ships. Errors of torpedo course also depended on the direction of attack—whether it was on the beam or right ahead, and it was difficult on a dark night to know if one was on the beam or not. Chances of hits were further dependent on the length of the ship and the angle she subtended. From this point of view, long ships were a disadvantage. The broad results of the experience of the Russo-Japanese War was that the gun-armed surface vessel had successfully neutralised the torpedo-armed surface vessel. That could broadly be said of the effect of the destroyer on the torpedo-boat.

These being the known war facts of the torpedo-armed surface-boat, the question arose, How did they apply to the submarine? There was no war experience of the submarine, but she carried the same weapon, and the same errors were possible. Some people might say that the submarine was safer for those on board than was the surface boat, and that their mental equilibrium would be less disturbed. But this was a peace idea. In peace manœuvres the man on the submarine knew that the man he was attacking would do him no harm. In war, he knew he would do his best to destroy him. This introduced an incalculable factor, and one must guard against drawing too definite ideas from peace practice. One must reserve judgment. The struggle was really one between weapons—between the gun and the torpedo—between a gun-armed surface vessel in motion and a torpedo-armed submarine, which must come to the surface at times and so expose herself to gun attack. He might suggest a simile. A fight between the gun-armed surface vessel and the torpedo-armed submarine was rather like a fight between a man in the open with a repeating rifle and a man under cover with a blunderbuss, who had occasionally to poke his head up to see what he was about.

Sir Philip Watts, the next speaker, pointed out that the author had stated there could be only two forms of defence against submarines—destruction of the submarines and protection of the bottom of the ship by armour. He had not appeared to think torpedo-net defence worth mentioning, but this defence could be made fairly effective, especially so when ships were stationary. A certain amount of protection could also be obtained by fitting deep inner bottom spaces, backed with tough protective plating, so that the loss of buoyancy resulting from a hit could be reduced to a minimum. Sir John had shown what it would involve if we had to armour-plate the sides of our ships to protect them against torpedo attack. If we retained the same speed, armour and armament as in the Dreadnoughts built during the last ten years, as many thought we should, the displacement would go up from 3000 to 4000 tons. The additional cost would be chiefly the cost of the introduction of the armour, which would be about 200,000*l*. These ships would still be somewhat smaller and, he believed, less costly than ships building at present by certain foreign Powers.

With regard to the points for discussion enumerated at the end of the paper, he would say:—

1. He thought 4-in. armour would afford sufficient protection against torpedos if associated with suitable inner bottom spaces, but it could be increased in thickness if desired.

2. Up to the present time the submarine menace had not been considered of sufficient importance to justify the adoption of armour protection on the bottom. Although discussed from time to time, it had never yet been seriously fitted.

3. He could not think that the power of gun attack was now relatively less than that of torpedo attack, but the reverse, and the importance of bringing the greatest number of big guns into the line of battle at least cost remained the same, and the value of speed remained the same. Hence the argument in favour of the big fast ship appeared the same.

4. It was probable that the admissible best form adapted for fitting and carrying armour would offer greater resistance than ordinary forms; but he was disposed to think there would not be very much in this. Resistance was very much more influenced by the longitudinal distribution of the displacement than by its transverse distribution.

Professor Hovgaard, who was the last speaker in the discussion, said that the problem discussed by Sir John Biles in his interesting paper was one of extreme importance, for on its solution depends the future of the large sea-going battleship. The question of the obsolescence of the battleship is really one of gradual restriction in its field of usefulness. Many people think that the battleship will be suddenly and absolutely abolished, and this idea has been advanced on several previous occasions when new weapons have appeared, but he believed that if the battleship was ever abolished it would only be as the result of a gradual process, perhaps of long duration. The Russo-Japanese War showed that the battleship could not safely approach fortified harbours, because the dangers of attack by floating mines were at all times very serious. In fact, the greater part of the losses by submarine attack during the war took place near the fortified places. At some distance from the coasts the battleships were fairly safe, being well prepared to meet the attack of surface torpedo craft. With the advent of the submarine-boat, the field of operation of the battleship at once became more restricted, although it cannot yet be said to what extent, since there is no war experience to go upon. It seemed certain, however, that large battleships would not now venture into narrow seas or near the coasts of an enemy unless they were absolutely forced to do so. For instance, he did not believe that they would

venture into the Baltic if this sea was infested by the submarines of a powerful enemy, but, if they did, they must certainly operate with the greatest caution. The same remark applied to the Mediterranean, although with less force.

As yet the submarine did not threaten the battleship seriously on the ocean, and as long as this condition existed battleships must be built to control the ocean—that is, they must be of the largest class and armed with powerful artillery. When the ocean-going submarine is an accomplished fact our conclusion might be different, but we do not know when this will happen, and perhaps by that time we shall be better able to meet submarine attack. It would be premature now to anticipate a danger that does not exist, and commence to construct small, poorly-protected and weakly-armed vessels. Battleships should be constructed to meet existing conditions, and not conditions that may not be realised for a number of years. The question is then, How best to protect the large battleships against submarine attack?

There are two positive ways in which this may be accomplished. One is by means of armour, the other is by means of the so-called "elastic" bulkheads—*i.e.*, bulkheads of curved form. Bulkheads of this nature were referred to by Mr. Owens in his paper read before the Institution of Naval Architects last spring, and are used by the French in the battleships of La Bretagne class.

Armour was now, as far as he was aware, always placed inside the ship on a longitudinal bulkhead at a certain distance from the outer shell. It was easy to show, however, that as now ordinarily constructed, this form of protection is unsatisfactory. Usually the armour is of 1½-in. or 2-in. thickness, and is supported only by a system of light stiffeners, quite out of proportion with the strength and weight of the armour itself. Probably the stiffeners will give way under the explosive pressures long before the plating is seriously strained, and the bulkhead will be blown bodily inwards. But even if the stiffeners are of adequate strength, it is likely that bulkheads as now constructed will give way by opening at the seams and butts and along the boundaries. It is very difficult, heavy and costly, to give sufficient strength to these lines of weakness. Let it be supposed, however, that this is done; then the armour-plating itself, being plane, will ultimately give way by bending, cracking, or tearing at the stiffeners long before it has had a chance to offer a resistance proportioned to its great weight and strength. On the whole, armour is ill-adapted to resist gaseous pressures; it is much better suited to resist local forces of great intensity, such as those due to the impact of projectiles.

As regarded armour placed on the outer shell, Professor Hovgaard went on to say that in 1909 he wrote an essay on this subject to Jane's *Fighting Ships*, where he gave a full discussion of this problem, resulting in the conclusion that if armour is to be used at all, it should be applied externally rather than internally. An explosion tends to expend its energy chiefly along the line of least resistance, a principle that is well illustrated in a gun. There the energy is almost entirely expended in giving forward velocity to the projectile and to the gases. The work done towards the rear by the recoil, where the resistance is much greater, is comparatively small, and laterally—*i.e.*, normal to the unyielding walls of the barrel—no work is done. Analogous conditions exist when a mine or a torpedo explodes in contact with the outer shell of a ship. If the side is unprotected, it offers practically no resistance, and the explosive pressures will be relieved instantaneously by exhaust into the interior of the ship, where they may cause widespread destruction. If, on the other hand, we could offer a greater resistance at the outer shell than that due to the inertia of the water, the explosive energy would be entirely or largely expended upwards into the atmosphere, since the line of least resistance would then be found in that direction. We cannot, of course, prevent a hole being punched in the side near the centre of the explosion, but by fitting armour on the side we may limit the size of this hole in a great measure. Only experiments can tell us to what extent this is possible, and how external armour will compare with internal armour. As already stated in his aforementioned essay, it is of the greatest importance that such experiments should be undertaken. In 1910 he contributed another essay to Jane's *Fighting Ships*, in which he recommended to fit 4-in. external armour on the outer shell, and to make the bottom, as far as possible, plane or developable. He recommended a form of the bottom somewhat approaching to that of a flat-iron, in order to facilitate fitting the armour, but as Mr. Ellis now stated that this difficulty no longer existed, it is best in that case to adhere to ordinary ship-forms. Hence, by fitting armour on the outside there appeared to be a possibility of keeping the greater part of the explosive effects outside the ship by giving the gas pressures time to exhaust more completely into the atmosphere. There is the further advantage that a good support of the armour is obtained without extra expenditure of weight, since the system of transverse and longitudinal frames in the double bottom can easily be made to offer a very considerable resistance.

His conclusion was, then, that if armour is to be fitted at all, it should be fitted on the outside; but he believed that the "elastic" bulkhead offered a far better solution of the problem. A crude calculation and even a simple consideration would show that it is possible with light plating of curved form to obtain enormous strength against gaseous pressure. Plane surfaces are, of course, entirely unfit for this purpose. No one would think of constructing a steam boiler as a rectangular box with plane walls. Even with ¼-in. plating it is easy to construct a bulkhead that will resist a head of several hundred feet of water. Such a bulkhead might be fitted at a moderate distance, perhaps from 8 ft. to 10 ft. inside the outer shell, and still be sufficiently strong. One important condition is, however, that it shall be adequately supported by deep girders. The elastic bulkhead would, he believed, essentially solve the problem of under-water protection, but it might be advantageous, in addition, to give to the outer shell a substantial thickness—for instance, 1 in.—and to construct it of a tough, high-tensile material, capable of being caulked, and well connected at seams and butts. This, however, was again a question that could only be settled by experiments

The Marquis of Bristol, in calling on Sir John Biles to reply to the discussion, regretted there was no torpedo admiral present to give his side of the question. Sir Reginald Custance and he himself were both gunnery officers. It was clear from the paper that it would be possible to fit protective under-water armour, but the interesting question was, Would this armour give the protection aimed at? In any case, he was afraid it would be necessary to retain the present speed and armament in conjunction with the new armour. It appeared to him, in a practical sort of way, that one should have an inner skin and some sort of cushion which would more or less damp out the explosion before it reached the armour. Finally, he thought it the duty of the Admiralty to carry out experiments on this question.

Sir John Biles, in reply, said that the paper had had the effect he intended when writing it. It would be agreed that no opinion had been expressed that the battleship should be eliminated. He thought this a fact worth recording in connection with the meeting. A second point was that it seemed to be agreed that some sort of under-water protection was possible—say 4 in. outside, or 1 in. inside and some outside, or some such arrangement. A third point was the desirability of doing this. That, he thought, must be left an open question at present. None the less when one remembered the screen of destroyers and cruisers round a fleet could be completely penetrated by submarines, which it never could by destroyers, the question of such protection became of great weight. The question might become acute in the near future, and he agreed with Lord Bristol that it was the duty of the Admiralty to consider the question very seriously. The consideration of the Paper then terminated with the usual vote of thanks.

The Föttinger Hydraulic Transformer.

At this stage of the proceedings the meeting was divided into two sections, and in the King's Hall, Dr. Föttinger read a paper on "Recent Developments of the Hydraulic Transformer," which we hope to publish in an early issue. Results were given of recent installations, and this, the author claimed, led to the conclusion that the economy of this system of power transmission and reduction resulted in an economy higher than that of electric transmission, and only 4 to 5 per cent. lower than that of mechanical gearing for ahead motion for the same steam conditions. For reversing and manœuvring its power and economy were over 100 per cent. better. Furthermore, by eliminating the astern steam-turbine, a decisive step in economy was obtained by utilising high superheat on board ship. The chief features of the system were:—(1) Increased speed and economy for all service conditions; (2) increased size of units both in ships and engines; (3) increased comfort and luxury for passengers and crew, due to entire absence of noise and vibration; (4) increased safety against danger, due to rapid manœuvring; (5) increased life of turbine-blading, due to constant rotation and absence of water-hammer and boiler-priming. In so far as the turbine was concerned, temperatures of 650 deg Fahr. could be safely used, a temperature which was now common practice in large stationary power plants.

Mr. Summers Hunter, who opened the discussion, acknowledged the free and frank manner in which Dr. Föttinger had placed his valuable experience before the Institution, and observed that the paper bristled with suggestions and valuable information. There were a few points which appealed to him as one identified more with merchant engineering than with warship work. Reliability and efficiency were what they asked for. Warships passed their trials at high power, and after that it was only in the stress of battle, when the lives of those on board were at stake, that the machinery was run at its maximum rate. With the merchant vessel it was quite different. Day after day, voyage after voyage, long or short, continual speed must be maintained, and he was sure it must be the admiration of everyone to notice the regularity with which our largest Atlantic liners and long-distance vessels performed their work at what was practically their maximum power and speed. It might be that under sea-going conditions some efficiency might have to be sacrificed to secure the reliability for which shipowners asked. From the shipowners' point of view, the question of cost was of primary importance. He was afraid that it did not matter how much economy they offered the shipowner, he would like the vessel at the same cost as the preceding vessel. It was a difficult position to meet, but he ventured to say new conditions were prevailing, and that, as opportunities arrived, the shipowners who were up to date were not afraid to spend a little more money to get what was so desirable—economy and efficiency. These were the considerations which must be taken into account in appraising the value of power transmission systems. As regards superheating, although he had done much in its adoption in merchant ships, he feared that, for the present, 650 deg. Fahr. was an excessive temperature.

Mr. R. J. Walker said that Dr. Föttinger was to be congratulated upon the success which had attended his efforts in the development of hydraulic transmission. The high efficiency which he obtained bore testimony to the good work he had accomplished in the transmission of power on hydraulic lines. He (Mr. Walker) was afraid that time would not permit him to deal fully with the many points raised in the paper, and the arguments used by the author in support of hydraulic transmission when compared with direct coupling of turbine engines to the propeller shaft or with mechanical gearing, and he would therefore confine his remarks to the few more important questions.

As regards efficiency, he thought it was generally accepted that the loss due to transmission alone was at least 8 to 10 per cent. greater with hydraulic transmission than with mechanical gearing. Attempts were made to reduce this difference to about half the amount by certain estimates of losses and gains which might be summarised as follows:—(1) Windage losses of astern turbines when revolving in the ahead direction. (2) Loss due to thrust-block. (3) Increase in the over-all efficiency with hydraulic gears by using the heated water of the transformer to increase the temperature of the feed-water.

With regard to windage losses in astern turbines, Mr. Walker said this question was fully dealt with in the discussion on Sir Charles Parsons's paper on "Mechanical Gearing for the Propulsion of Ships," read at the spring meetings of this Institution last year; but he would like to refer to an experiment which had recently been carried out at the Turbinia Works, Wallsend, by Mr. Cook (one of his colleagues at the works), on the windage loss of astern turbines in a geared installation recently

constructed. The arrangement of machinery consisted of one high-pressure and one low-pressure turbine, with an astern turbine incorporated in the exhaust casing of the low-pressure turbine, the turbines being coupled to the propeller shaft by means of mechanical gearing. The total ahead power transmitted to the propeller shaft was 3600 shaft horse-power. The revolutions of the turbines were 1486 per minute, revolutions of propeller shaft 90, so that the ratio of gear was 16.5 to 1. The astern power was 60 per cent. of the ahead power (with the same quantity of steam). A new rotor was constructed carrying only astern blading and rotated in the fully-bladed turbine casing at varying speeds and vacua. The power was supplied by an electric motor and measured in the usual way. The results showed that with the turbines revolving in the ahead direction at a speed of 1500 revolutions per minute, the loss was $10\frac{1}{2}$ horse-power, or $\frac{3}{10}$ of 1 per cent., with a vacuum in the condenser of 28 in., and 21.5 horse-power, or $\frac{6}{10}$ of 1 per cent., with a vacuum of only 26 in., thereby confirming the figure given by Sir Charles Parsons in his reply to the discussion on the paper already referred to—namely, that when going ahead the astern turbines are revolving in the vacuum of the condenser, and under such conditions the loss was not more than $\frac{1}{2}$ of 1 per cent. This result also confirmed Mr. Allan's experiments on windage loss of astern turbines.

With regard to the second point, in the later ships fitted with mechanical gearing pivoted thrust-blocks were employed, thereby reducing the losses in thrust-block friction to about $\frac{1}{10}$ of 1 per cent., practically a negligible quantity. As to the third point, in most of the modern turbine vessels the exhaust steam from the auxiliary engines was utilised for heating the feed-water. The quantity of exhaust steam available was in most cases quite sufficient to increase the temperature of the feed-water to 200 deg. or 220 deg. Referring to the question of the regeneration of heat, Dr. Föttinger gave the increase in over-all efficiency of the transformer due to feed-heating as 1.5 to 2 per cent.—this implied a loss in the transformer of $7\frac{1}{2}$ to 10 per cent. of the brake horse-power of the turbine. It was also said that for poorer efficiencies even 3 to 4 per cent. more could be gained. By a simple calculation it followed that if it were possible to obtain more than double the increase in the efficiency due to this regeneration of feed-heating, there would be in these cases double the initial loss in transmission.

Referring to the question of propeller efficiency, it had always been admitted that with direct-coupled turbines some sacrifice had had to be made in propeller efficiency as well as turbine efficiency, and that it had been necessary to compromise between the two. It was true that in some large-powered high-speed vessels propulsive efficiencies with direct-driven turbine propellers had been obtained approaching that of vessels with piston-engines; but in making any comparison of propulsive efficiency, as naval architects well knew, a very careful examination of the conditions and factors affecting propulsive efficiency required to be made. An error frequently encountered in the early stages of the development of the turbine-engine was to compare the propulsive efficiencies between a turbine-driven ship and a vessel with piston-engines, taking the shaft horse-power in the former case, and the indicated horse-power in the latter, whereas a correction should have been made to bring the piston-engine to a common basis of shaft horse-power.

Generally speaking, it was quite possible with reduced revolutions of propeller to obtain an increase in propeller efficiency varying from 5 per cent. to at least 12 per cent. in the different classes of ships where the direct-driven turbine had hitherto been successfully applied. With mechanical gearing, where the ratio of gear was not limited as in the hydraulic transformer, then full advantage could be taken of this increase in propeller efficiency to reduce the shaft horse-power necessary for a given speed. This reduction of power, together with the increase obtainable in the efficiency of high-speed steam-turbines, permitted of a considerable reduction in boiler power, size of auxiliaries, and condensing plant.

With the ratio of gear to which the hydraulic transmitter was limited it would appear that it was confined to a somewhat narrow field of work, inasmuch as it was not possible to secure in the majority of cases the accommodation necessary between the speed of the turbine and the speed of the propeller for maximum efficiency of each. There was therefore, in addition to the loss in transmission, a further loss in the propulsive efficiency with hydraulic transmission when compared with mechanical gearing, and the difference in over-all efficiency, when referred to in "knots run per ton of fuel," had been found to be very considerable in designs for war vessels.

He did not think that Dr. Föttinger had established any of the claims set forth in his conclusions. The question as to whether larger units incidental and necessary with hydraulic transformers were an advantage he thought was very much open to doubt. The placing of turbines in series on a common gear-wheel, instead of an independent turbine, had many advantages in favour of its recommendation; it was more economical in steam consumption, and the units were much smaller and more accessible, and in the event of a turbine being temporarily deranged, suitable pipe connections could be arranged for the working of the other turbine. In recently-constructed gears, which had been cut on the "creep" principle, noise had been practically eliminated. There was no difficulty in arranging for an astern power of 75 per cent. that of the ahead, should it be desired; but for all practical purposes it had been found that 60 per cent. of the ahead power was ample for any condition of manœuvring, and all recent designs of geared turbines provided for an astern power of at least 60 per cent. of the ahead for the same quantity of steam. Dr. Föttinger had suggested that astern turbines were a source of trouble. This was not the case. No trouble whatever had been experienced by the heating up of the ahead blades when driven in the opposite direction at full speed. The ahead turbine was connected to the vacuum of the condenser when going astern. It was observed in the illustration accompanying Dr. Föttinger's paper that an additional transformer was required for astern purposes in lieu of the astern turbine.

There was no difficulty in using superheated steam in geared turbines, either ahead or astern, provided suitable materials were employed in the construction, such as cast steel, instead of cast iron, for the high-pressure parts of the turbines. As a matter of fact, there were several geared-turbine installations under construction, arranged for superheat of 100 deg. to 150 deg. Fahr.

Dr. Föttinger, in replying, asked if Mr. Walker had seen the transformer plant at work, to which Mr. Walker replied in the negative. Continuing, Dr. Föttinger said he was afraid that Mr. Walker spoke on figures which had now been surpassed by the new results. There were, he said, other ways of looking at an engine besides the 5-per-cent. economy, and that from this point of view the hydraulic system merited consideration. He did not claim that what he had propounded was the solution for all questions and problems, but he proposed to show in future that this contribution, though a modest one, was a positive contribution to international science.

This section then adjourned after a vote of thanks to the author of the paper had been passed.

Shipbuilding Practice.

In the Physical Lecture Theatre, to which part of the meeting had adjourned after the conclusion of the discussion on Sir John Biles's paper in the King's Hall, two papers were taken, Sir Philip Watts being in the chair. The first was by Mr. J. G. John, and was entitled "Shipbuilding Practice of the Present and Future." It was read by its author. We reprint the paper on page 68 of our present issue.

Sir William Smith opened the discussion. He thought the meeting was to be congratulated on having listened to such a very able paper. Mr. John had gone into his subject in a very exhaustive way, and had written a valuable chapter on the question of how to get value for your money, which was, after all, the main problem in most walks of life. Many people seemed to think that when the Admiralty was in question, any difficulty encountered could be met by getting a little more money; but things did not work out like that. In this connection he would say that during the time he was at the Admiralty he went fairly closely into the question of pneumatic riveting, which was dealt with in the paper. He agreed with the author that it could be satisfactorily done, even for large rivets, if the people doing it wanted it to be satisfactory. But if one wanted to scamp work, it was easier to do it with pneumatic than with hand riveting. Mr. John's reference to the joining of parts by riveting was an apt illustration of the thorough way he had considered things in writing his paper. He (the speaker), like many others, had taken the joining of parts by riveting as a matter of course, but, as Mr. John had showed, there was nothing fundamental in it.

Colonel Saxton White said the paper was a very important one. If anyone called upon to lay down a new shipyard had the paper before him, he would learn to avoid many things which he ought to avoid. Those present at the meeting would that afternoon have an opportunity of seeing a yard which, he thought, would appeal very favourably to shipbuilders. One feature of lay-outs which appealed very much to his mind was the avoidance of the crossing over of traffic. This feature had been adopted in the yard they were to see. On the question of pneumatic riveting, he admitted there were difficulties, but thought they would be got over. Power riveting must inevitably be more and more introduced. He was interested in Mr. John's idea of welding the shells of steamers. If one could erect the plates in position, with the edges suitably prepared, and then weld them all up, it would be a consummation devoutly to be hoped for. All the same, he thought we should long have to rely on our friend (some called him something else) the riveter.

The crane question had been dealt with in an interesting way in the paper. That afternoon the audience would not see any covered berths, but would see a crane equipment that had the valuable property that it could be transported within certain limits to a new position. This was a most important matter. Owing to the size and character of ships constantly changing appliances frequently became obsolete. He could refer to sheds over shipbuilding berths, not 100 miles from the Hall, which were now too small for the work it was desired to do. It was important that, as far as possible, shipyard arrangements should be made elastic. A builder who put down certain plant at once of necessity limited the size and type of work he could undertake.

Mr. Rowell wished to know if Mr. John could say rather more about the process of welding he had used than he had put in his paper. The reference to the elimination of riveting was most important. It seemed to promise greater efficiency than at present for the expenditure of a certain number of tons of steel. The question of a welded ship was a big one, but the welding of the butts of plate-seams did not seem an impossible one, and would be an important step. On the question of lifting appliances for shipbuilding berths, he would say that he went into the matter fairly fully some years ago, and the result showed that it was not possible to justify an expenditure of more than 4000*l.* per 100 ft. of berth. This seemed considerably below some of the figures in the paper. He was sorry he had not seen Mr. John's paper earlier, and so had more time to consider it.

Mr. P. A. Mudd, of West Hartlepool, wished to say something on the part of the paper which dealt with electric welding. For some time past he had been engaged in carrying out electric welding repairs, and might be able to make some useful remarks. Electric arc welding dated back to 1885, when Nicholas de Bernados, of St. Petersburg, took out his patent for carbon arc welding. At that time, 29 years ago, Bernados saw a number of uses for his process, and in his specification mentioned a variety of plate-joints to be made, without rivets, either by point or continuous welding. He also claimed the construction of iron and steel vessels, boilers, armour-plate, and hydraulic apparatus, all welded at the joints and without rivets. In the result, however, little progress was made with carbon arc welding. The reasons were the difficulties of excluding the atmosphere and avoiding oxidation during the weld, and also of obtaining proper heat regulation of the arc. The welded or fused metal resulting from the process was extremely hard and full of small pores.

In the last few years considerable progress had been made in arc welding with metal electrodes coated with a flux or slag-forming composition. In the "Quazarc" process the difficulties of oxidation and heat regulation were faced in this way. In addition to protecting the fused metal from oxidation, the slag which was formed acted as a secondary conductor, and appeared to damp down the heat of the arc more nearly to the welding

heat required. Too much heat caused the metal to run very liquid and fly about, increasing the oxidation difficulty. Too little heat meant the added metal did not unite to the mass of the work. In the repair-work with which he (the speaker) had been concerned a word had been coined to express the right heat, and when the work and the added metal ran together "treacly," then the welding heat was right. It was obvious that downward welding gave the best results—that was work in which the molten metal from the electrodes ran down on to the work and the slag could float on the top, and so prevent oxidation. Unfortunately, in practice only about half the work necessary could be carried out downwards, the other half being either vertical or overhead. Overhead work was the most difficult, and taxed the skill and patience of the welder to the utmost.

He would like to make a few remarks on the results submitted by Mr. John. He would ask if the test-pieces referred to were welded on the bench under the best conditions of downward welding. He presumed they were. In the A series, when the tensile strength and elongation were tested, there was no actual test of the solid bar given for comparison, and also there was no tensile strength and elongation of the electrode wire which had been used. It was obvious that if one welded a 29 to 30-ton tensile boiler-plate with 24 to 25-ton wire electrodes, one could expect to get only about 75 to 80 per cent. of the strength of the solid plate in the weld. The sketches in the paper showed camber at the weld increasing the section. He presumed this was machined off before testing. A further point was that it was not stated if the butt was welded from one side only or from both sides, and whether the added metal was hammered while hot. In practice it was not always possible to weld a butt on both sides, but when it could be done it made the best job. It would have been better had Mr. John given an average over more than two test-pieces, one of which broke at 22 tons and the other at 25 tons. These were both good results. The conspicuous feature of tensile tests of welding was the lack of ductility shown by the small elongation of 3 to 6.5 per cent. obtained, although in the bending tests of all the series given the results were good. Further tests were required to determine resistance to fatigue.

In recent years electric welding had been used extensively for repair work on boilers and ships, but was very little employed for new work. For repair work on boilers it was much used for building up landing edges of riveted seams which were leaking, for welding in new patch-plates, for welding cracks in plates, and for building up wasted and corroded parts to their original thickness. For ship repairs it was used for welding landing edges of leaky seams, such as box-keel plates to stern-posts, welding cracks in stern and rudder-posts, welding split rudder gudgeons and building up worn rudder pintles. In the application of electric welding to new work, the speaker believed there was a large possible field, commencing on small work, such as steel water tanks, oil tanks, exhaust tanks, welded steel-plate condensers, and welded steel-plate masts and derricks. In the main structure of a ship, when watertightness was required in certain parts liable to corrosion, the landing edges of the riveted seams should be welded solid to do away with the caulking, which in time became leaky.

Mr. T. G. John, in replying to the discussion, said that when considering the preparation of the paper he had been struck by the rarity of papers on the subject. He thought the subject could not have been discussed in a better place than Newcastle. Colonel Saxton White was in a happy position in laying out his new yard. Most people could not afford all that had been done in this case. Such things as movable tower cranes and the non-crossing of traffic were usually impossible owing to the exigencies of the site. He did not altogether understand Mr. Rowells's reference to the cost of crane plant. Many figures in the paper were below that which Mr. Rowell had quoted. In reply to Mr. Mudd, he would say that the test-pieces dealt with in the paper were welded when in a horizontal position. Vertical welding had been done, but the results were not quite so good. The welds were not hammered. Hammering would obviously have improved them. He would also say that the strength of a weld must clearly depend on the strength of the material deposited.

A vote of thanks was then passed to Mr. John for his paper, on the motion of the chairman, and consideration was turned to the next contribution. This was a paper by Mr. G. H. Millar, entitled, "Some Notes on the Design of Floats for Hydro-Aeroplanes." It was read by the author in abstract. The paper, which we hope to reprint later, dealt with recent work on the subject carried out at the National Physical Laboratory. We need not deal with the paper now, as, in the absence of time, there were no remarks on it, beyond some congratulatory sentences by Sir William Smith, who rose on the invitation of the chairman. This concluded the proceedings of the morning.

Excursions.

In the afternoon the ladies of the party had a trip by train to Alnwick Castle, the seat of the Duke of Northumberland, K.G., while a large number of the gentlemen proceeded to the new Armstrong Works of Messrs. Sir W. G. Armstrong, Whitworth and Co., Limited, which were described in last week's issue (page 1 *ante*). Luncheon was served, and Sir Andrew Noble, having proposed the loyal toasts, welcomed the members of the three Institutions Earl Brassey replied, and Sir Charles Parsons proposed the chairman's health. After inspecting the yard, the members proceeded by steamer to Messrs. Swan, Hunter and Wigham Richardson's works, being received by Dr. G. B. Hunter. The most important object of interest was a four-cylinder four-stroke-cycle single-acting Diesel engine, running on the test-bed and developing 600 horse-power. The fact that fourteen vessels, including a light armoured cruiser, a destroyer, and every type of merchantmen, were in progress on the stocks, and that four vessels were afloat being completed, served further to show the importance of the work being done by the firm.

In the evening a reception was given by Sir Charles Parsons, chairman of the Council of the North-East Coast Institution of Engineers and Shipbuilders.

Warships Built at Elswick.

On Wednesday the proceedings were arranged by the North-East Coast Institution of Engineers and Shipbuilders, and two meetings were held. That in the Lecture Theatre of the Literary and Philosophical Society was under the chairmanship of Sir Charles Parsons, President of the Institution, and the first paper read was by Mr. J. R. Perrett, the Naval Constructor of Sir W. G. Armstrong, Whitworth and Co., Limited. The title was "Some Notes on Warships Designed and Constructed by Sir W. G. Armstrong, Whitworth and Co., Limited." In it Mr. Perrett described the vessels designed successively by Mr. George Rendel, Sir William White, Sir Philip Watts, and himself since 1867, and built first at the Walker yard, and since 1884 at Elswick, and now also at the new Armstrong yard. It is scarcely necessary in the present day, and with the full knowledge existent of the influence of Elswick designs on the development of the warship as we know it to-day, to indicate the features of the large number of vessels built. It may suffice, as some indication of the extent of this influence, to state that since 1884 the firm have constructed, or have in hand from their own designs, 64 warships, 59 being on foreign account, whilst five were built for or acquired by our own Government. These 64 vessels included 15 battleships, 33 cruisers, five torpedo-boat destroyers, three armoured gunboats, six scouts, and two training ships. The Turkish Royal Yacht and State Barge were also designed and constructed at Elswick. The total displacement of the ships amounts to 365,463 tons, and the total horse-power of the machinery fitted in them to 756,706. Added to the remainder of the warship output, these figures become respectively 619,979 tons and 1,221,687 horse-power.

At one time—in 1896—the firm had simultaneously in process of construction twenty warships of different classes, fifteen being under construction at Elswick and five at Walker. This list included a 12,300-ton battleship, two first-class armoured cruisers, each of 9700 tons, one armoured cruiser of 8500 tons, one armoured cruiser of 7000 tons, two coast-defence armourclads, each of 3400 tons, eleven second and third-class cruisers, and two torpedo-boat destroyers. The aggregate displacement of these vessels amounted to 98,000 tons, and six of them were launched from Elswick during the year mentioned. At the present moment the firm have in hand ten war vessels, of a total displacement of 158,670 tons, comprising five Dreadnoughts, two coast-defence armourclads, two scouts, and one armoured gunboat.

Sir Charles Parsons, in inviting discussion, referred to the work done by the Tyne Commissioners in improving the river to enable increasingly large ships to be launched and navigated to the sea.

Admiral Sir Reginald Custance said that they all must be impressed by the greatness of the work accomplished at Elswick, and he thought the author might look with pride on the part he had taken in the work which had been done. His memory went back many years, and he knew of the difficulties which the celebrated men connected with the firm had had to contend with in striving to meet the views of the naval officers of the day. It was very difficult, because the questions were far from being thought out, and, in consequence, mistakes were made. For example, they might refer to the Victoria. There was no doubt that the design was faulty in principle in several particulars, and no one would dream now of producing such a design. Without dwelling on further mistakes of which they knew, he ventured to suggest that they might not be altogether right in everything they did at present. Distinguished men in the past made mistakes. Might not they now also be making mistakes? Might not the first general action bring out their errors, and might they not have to reconsider some points? He would not stop to speak of them, beyond referring to the contest between the gun and the armour. The gun had always been kept to the forefront by the Elswick firm. The late Lord Armstrong was a firm believer in it as against the armour, and he observed in the paper that had just been read that the Elswick firm was applying much thinner armour to the ships than the Admiralty. He believed the maximum thickness of the broadside armour of the Chilian vessels was 9 in. He compared that with the 13½-in. armour of the Malaya, and he congratulated the firm on this step. He ventured to point out that they were adhering to the ideas of Lord Armstrong, and they had his support very cordially.

Mr. Perrett pointed out that in the ship which they were now laying down for a foreign Government the broadside belt, as mentioned in the paper, was of 13½ in. in thickness.

Sir Philip Watts said he had been more or less closely associated with the Elswick shipbuilding department for most of the period covered by Mr. Perrett's paper, having first visited the works in 1870. Several of the most important advances in modern warship design had been due to Mr. Perrett. In the manuscript copy of Mr. Perrett's paper, which he had read, but which had been modified, comparisons were made between Elswick-designed ships and other ships built at the same time, which showed that Elswick had on occasions taken the lead in warship design. Mr. Perrett, no doubt, had his own reasons for not bringing up such points in the printed paper—comparisons they knew were odious—but they might, in this case, be made by anybody who was sufficiently interested in the matter to do so. When he became manager of the warship department at Elswick, in 1885, the new shipyard was pretty much in the same position as the new Armstrong yard now was. In arranging the new yard, Mr. Perrett and his assistants had set to work upon an excellent arrangement of berths and shops, with the most modern and improved appliances, and he believed the yard was second to no other yard in existence.

Mr. W. H. Whiting observed that Sir Reginald Custance, with his usual insight, had set his finger at once on the two important lessons which were to be derived from this paper. The first was the true judgment with which Lord Armstrong constantly emphasised the predominant importance of attack over defence, and his insistence upon the power of the gun, even, he must admit, in one or two cases where special considerations rendered his design open to criticism. Secondly, such a review as that given offered a warning that they needed at the present time to apply to current ideas the closest analysis and severest scrutiny, lest they might be found, perchance, to be following a similar course to their predecessors, and pushing on with ideas which a later judgment might throw great doubt upon. The only other point to which he wished to refer was the reference which Mr. Perrett made to the

great service rendered, not only to the firm and to the Tyne, but to the country, by Mr. George Rendel. The paper seemed to imply that Mr. Rendel's first essay in shipbuilding was the design of the first Esmeralda. His first effort was the gunboat Staunch, the first vessel produced at Walker, a very little vessel, with a 12½-ton gun mounted on a disappearing platform, and acclaimed at the time by a large body of opinion to be a great success. Large numbers of such vessels were built in succeeding years in Government and other dockyards.

Mr. G. J. Carter expressed the pleasure it had given him for so many years to be associated with Mr. Perrett in the work at Elswick. The work carried on there had certainly been of a very progressive character, and, he believed, under present management, would continue to be so.

Sir William Smith said that from the beginning of the warship construction at Elswick he was closely connected with the work from the Admiralty point of view. He could say, from contact with the officers of the Elswick firm, that while they were hard bargainers, they had not had any outstanding question but what could be settled by amicable discussion and without higher authorities having to be evoked. That, he thought, bearing in mind the supervision exercised by the Admiralty, and the way in which the work done by the Admiralty came under the review of the Public Accounts Committee, was an exceedingly good record for the firm.

Mr. A. Scholfield (Tyne Improvement Commission) said the Commission naturally took the very greatest interest in the development, not only of the Elswick Works, but of all the vast industries on the river. It was with no little anxiety that they used to watch the development of the enormous vessels at Elswick, more particularly with regard to their beam, because they realised that there would be difficulties in the passage under the high-level bridge and through the swing bridge. Therefore they were delighted at the developments at Walker, because it got rid of these difficulties. The shipbuilding companies generally might think the Commissioners were hard to get on with in regard to encroachments, but the river was extremely narrow, and they had what they called a "river line," and they would adhere to it in the interests of all.

Mr. James McKechnie referred to the great enterprise of the Elswick firm, and, in speaking of the new Armstrong yard and its admirable and extensive equipment, ventured to raise the question of the difficulty of finding experienced workmen to carry on operations under present conditions.

Professor Hovgaard pointed out the epoch-marking ships built at Elswick. There was the Esmeralda. Apart from her high speed and great gun-power, she was the first notable cruiser without sail power, and the first cruiser with a complete armoured deck from end to end. The Piemonte had the four-cylinder engine, and was the first cruiser with a complete installation of rapid-firing guns. The Amethyst was distinguished as the first turbine cruiser, and the Victoria marked, at the period, the highest achievement in large-bore guns. Now they were reaching the maximum in another similar cycle in guns. He referred to the close association of the Elswick Works with Japan, remarking that it was the 4.7-in. gun which had won the battle of Yalu.

Sir Charles Parsons, in closing the discussion and proposing a vote of thanks to the author of the paper, mentioned the fact that he had served his apprenticeship at Elswick, and then formed the opinion that Lord Armstrong was one of the greatest men of the day. Subsequent events had only tended to confirm him in that view.

Mr. Perrett, in reply, surprised the meeting by remarking that the paper was his maiden effort in that direction.

Progress in Marine Steam Machinery.

Mr. A. C. Ross read the next paper, giving "A Review of the Progress in the Marine Steam-Engine on the North-East Coast During the Past Fifteen Years." It was a comprehensive, although brief, review, and in the course of it he said that, by the introduction of an all-geared installation in light cruisers of high power, it was quite possible and practicable to reduce the total weight of machinery to about 60 lb. per shaft horse-power, and, by the adoption of oil fuel, to get as much as 140 shaft horse-power per ton of boiler. In the case of destroyers with three shafts and geared cruising turbines, the corresponding figures would be about 33 lb. total weight of machinery per shaft horse-power, and about 190 shaft horse-power per ton of boiler. In 1899 the corresponding figures were about 220 lb. for total weight of machinery per shaft horse-power, and about 24 shaft horse-power per ton of boiler using coal for cruisers; and 56 lb. total weight of machinery per shaft horse-power and 97 shaft horse-power per ton of boiler using coal for destroyers.

Mr. A. F. Yarrow, who opened the discussion, referred to the work of Sir Charles Parsons, and said his name would be linked in history with those of Faraday, Watt, and Stephenson.

Mr. William Boyd, the first president of the North-East Coast Institution, said, in regard to oil-fuel, that that was the subject of the day, and the company with which he was identified—the Wallsend Slipway—had been connected with the industry for a great number of years. Somewhere in the 'eighties they engined a large number of small vessels for what was then the firm of Charles Mitchell and Co., for use in the Caspian Sea. The peculiarity was that the water in the Caspian Sea being fresh water, there was no difficulty in regard to the use of steam for the spraying of the oil.

Mr. John Thornycroft referred to the great change in the modern engine-room.

Mr. R. S. Portham said that Mr. Ross had referred to the excellent results of the Port Kembla, with quadruple engines and superheated steam, and wondered why superheat had not been more largely adopted in British ships. This was largely due to the prejudice of the pioneer British experiences of marine superheating of forty years ago, with uptake superheaters and vegetable oil of low flash-point. Germany started with a clean sheet, using the Schmidt system of superheater and high flash-point (600 deg. Fahr.) mineral oil. In Germany over 1,000,000 indicated horse-power was now running on the Schmidt system, the latest ship equipped being the 30,000 shaft-horse-power North German Lloyd steamer Columbus, and her sister-ship, having twin-screw quadruple engines. British owners were slowly, but surely, following Germany's example, and the results of forty ships fitted with Schmidt superheaters, aggregating 150,000 indicated horse-power, showed a net saving of 15 per cent and low maintenance costs, as compared with saturated steam. With geared reaction turbines and impulse-reaction astern turbines and superheat, an economy of 30 per cent. was realisable, as compared with reciprocating saturated-steam engines, and he prophesied that this system will be more and more adopted in the near future.

Sir Charles Parsons said he did not think that at the present time they realised what an important probable future the superheater had. In the old days they had the difficulty of the ingress of salt, but that had been largely got over by improvements in the manufacture of the tubes themselves. Then there was the question of the arrangement of the safeguards, so that in the various functions of the machinery on board ship there would be no possibility of the superheater getting burnt. The chief departure initiated in the Schmidt system had been the placing of the superheated tube in close proximity to the water surface in the boiler in order that the tubes would not reach a destructive temperature. He believed that the success of the superheater justified them in saying that its use would extend to a large extent. He further mentioned that Sir Philip Watts had been the first to urge the adoption of wide-bladed or large projected surface propellers with fine-pitch ratio for turbine driving.

Mr. Ross briefly replied, and the proceedings of the section terminated.

Internal-Combustion Engines.

At the meeting held at the Institution of Mining last Wednesday morning, simultaneously with that above reported, the chair was taken by Mr. Summers Hunter, and two papers were read—namely, one by Professor B. Hopkinson, entitled "The Charging of Two-Cycle Internal-Combustion Engines," and the other by Mr. H. F. Fullagar, entitled "A New Type of Internal-Combustion Engine." Of this meeting we are compelled by the demands upon our space to postpone our report until next week, when we shall deal with these papers and the discussions upon them.

Excursions.

The ladies attending the Conference went on a motoring tour on Wednesday, and were entertained at luncheon by Lady Parsons at Ray, Kirkwhelpington, and at tea at Cragside, Rothbury, the residence of Lord Armstrong. The gentlemen of the party went on one of five alternative visits of inspection. (1) To the works of R. and W. Hawthorn Leslie and Co. and Messrs. Palmers; (2) To the North-East Marine Engineering Company's Works; (3) To the Wallsend Slipway and Engineering Company's Works; (4) To the works of the Fullagar Engine, Limited; or (5) To the Consett Iron Works. In all cases the guests were entertained to luncheon. In the evening a reception and dance was held at the invitation of the Lord Mayor of Newcastle-on-Tyne.

Yesterday (Thursday) was given up entirely to social functions. In the forenoon alternative visits were made to the Darlington Forge, or to Messrs. Doxford's Works at Sunderland; and in the afternoon a large company attended a garden party at Lambton Castle on the invitation of the Earl of Durham, K.G., and Lady Anne Lambton.

To-Day's Proceedings.

The concluding meetings of the Conference are being held to-day, the programme of papers having been arranged by the Institution of Engineers and Shipbuilders in Scotland. The papers to be read are:—1. "Influence of Varying Temperatures on the Strength and other Properties of Admiralty Gun-Metal," by Professor A. Campion and Professor John G. Longbottom. 2. "The Strength of Welds by the Oxy-Acetylene Process," by Professor A. Campion and Mr. William C. Gray. 3. "Some Experiments on a Diesel Engine," by Mr. W. S. Burns.

(*To be continued.*)

NOTES.

Durability of Taps for Benzine Tanks.

Professor Alexander Baumann, of the experimental station for aeronautics and automobilism of the Technical High School at Stuttgart, has made some experiments on the durability of taps, greased and ungreased, when exposed to the flow of benzine. He fitted new taps into two vertical pipes, each 3 metres high; the upper portions of the pipes consisted of glass tubes, 4 mm. in internal diameter, behind which cardboard scales were fixed. By the aid of a mechanism the two taps were opened and closed simultaneously, fifty times in each series, and observations were taken half-an-hour later of the sinking of the benzine level. The one tap was greased, the other not. It soon appeared that very little benzine escaped through the greased tap, but a great deal through the ungreased tap. The experiments were repeated, and the greasing was renewed after six or seven series. The loss of benzine in the greased tap amounted generally to a few millimetres only—five, or less—and did not increase as the series were repeated; the greased tap improved, in fact, in the consecutive series. In the ungreased tap the loss amounted to 145 mm. in the first series already, and it rose to more than 1500 mm., not regularly, but steadily, while the tap began to drip. The details of the experiments, which were apparently not varied, are scanty, unfortunately. In the account which Professor Baumann gives in the journal the *Motorwagen*, of May 31, nothing is said about the nature of the pipe, of the tap, and of the grease used; it is merely stated that the grease was, or should be, insoluble in benzine. There is no doubt about the main fact, however, that suitably greased taps keep benzine-tight, and ungreased taps do not, but deteriorate more and more when turned frequently.

Conversazione at the Institution of Civil Engineers.

The Institution of Civil Engineers held a conversazione on the 2nd inst. in their new building, when the guests were received by Mr. Lyster, the President, and Mrs. Lyster, and a very full musical programme was admirably rendered. Several of the rooms—the south reading-room, the council room, and the committee room—had been set apart for the exhibition of engineering models and scientific apparatus. The exhibits numbered forty-nine, and covered metallurgy and civil, mechanical, naval,

and electrical engineering. We do not propose to review all of these in this short note, but following the order we have just stated, we may mention a series of rail specimens taken from the London County Council tramways, showing corrugations. Close to this was an interesting series of rail sections from the Great Western Railway, illustrating the development of the permanent way on that system since the year 1840. Sir Bradford Leslie, K.C.I.E., showed a model of a cast-iron pedestal sleeper, carrying reversible rails, as laid on the Jullunder-Doab extension of the Southern Punjab Railway. This pedestal sleeper does away with the notching of the lower head of the rail produced by bearing on the chair, and enables the rail to be reversed when the upper head is worn, thus doubling the life of the rail, the pedestal itself being practically imperishable. The pedestals are held together by a tie-bar provided with serrations for adjusting the gauge. Sir Bradford Leslie also showed a model of a cast-iron joint sleeper in which the rail ends are held. Another interesting specimen in the same room was the fractured tie-bar from the Charing Cross Station roof, showing the flaw in the centre, exhibited by Messrs. David Kirkcaldy and Sons, who also had an interesting series of fractured mechanical parts showing the growth of flaws. Mr. E. W. Timmis exhibited a model illustrating his system of bogie-lead and outside suspension swinging-bolster arrangements with bearing springs differentially loaded (see page 488 *ante*). Close to this could be seen the Gardner vibration signal for railways, exhibited by Mr. S. B. Cottrell. The portable apparatus, such as can be used by platelayers, consists of a box-shaped transmitter and a portable alarm in a case containing the battery, the transmitter being connected together by a twin lead as is used in field telegraphy. When a train reaches the place where the transmitter is laid, the vibration causes the alarm to ring, and it will continue to ring as long as the train is passing over the transmitter. The apparatus is also designed to give level-crossing warnings, to render audible a signal invisible through fog or smoke, and automatically to record the passage of trains. The models of the new marine station at Dover, of several bridges and locomotives, of the Pennsylvania tunnel shield, of a medical air-lock for the treatment of caisson disease, and of a Temperley grab-transporter in action, and of cranes, attracted general attention. Among the crane models we may mention Messrs. Stothert and Pitt's electric luffing-crane, of which we gave an illustrated description in our issue of the 26th ult.; also two models of luffing-cranes shown by Mr. Arthur Musker, with jib balanced by weights in one case, and by the engine cylinders in the other. Messrs. R. Waygood and Co. had a nicely-finished model of one of their automatic electric lifts in action, illustrating the means which render it automatically safe in working. A working model of a lighting equipment for a "National" steam-omnibus, with grate section showing rocking-bars and coke-feeders, was exhibited by Mr. Thomas Clarkson. The equipment contains sufficient coke to allow for the vehicle a run of 50 miles, the coke surrounding the boiler. Mr. A. F. Yarrow showed models of his device to facilitate the coupling of cruising turbines, particulars of which were given at the Glasgow meeting, last year, of the Institution of Naval Architects (see ENGINEERING, vol. xcvi., pages 11 and 26). He showed also a model of his latest balance-flap fitted to the end of the tunnel in which the propeller works, for very shallow draughts. We gave an illustrated description of this device in a former issue (see ENGINEERING, vol. lxxv., pages 498 and 512). A Michell thrust-bearing, sent by Mr. H. T. Newbiggin, formed also part of the exhibits; this bearing we described in our last volume, page 179.

THE NORWEGIAN NAVY.—The Norwegian Parliament has voted a grant towards an extension of the dockyard at Horten for the purpose of there building two submarines and two hydroplanes and to commence the manufacture of Diesel motors, for which the Councillor of State in charge of the question stated that drawings had been obtained from a foreign firm.

FLOATING-DOCK AT WILHELMSHAFEN.—A floating-dock of 40,000 tons capacity has just been built at the Blohm and Voss yard, Hamburg, for Wilhelmshafen; it has been transported there in pieces, and Wilhelmshafen now boasts four large floating-docks. Another floating-dock of about the same dimensions is at present in course of construction at the same yard for the naval station at Kiel.

NOTES FROM THE NORTH.

GLASGOW, Wednesday.

Glasgow Pig-Iron Market.—Last Thursday there was a want of life in the Glasgow pig-iron market, and no dealings of any kind were recorded. At the opening session there were sellers of Cleveland warrants at 51s. 1½d. cash, 51s. 3d. one month, and 51s. 5d. three months, and at the close of the afternoon session these quotations were unchanged. On Friday morning the market remained in a dull condition, and no business was transacted. Closing sellers of Cleveland warrants quoted 51s. 1½d. cash, 51s. 3d. one month, and 51s. 5d. three months. A better tone prevailed in the afternoon, but only one lot of Cleveland warrants was put through at 51s. 2d. cash. Prices became a little firmer, and at the close sellers quoted 51s. 2½d. cash, 51s. 4½d. one month, and 51s. 6d. three months. On Monday morning the tone was again fairly strong, and 1000 tons of Cleveland warrants were done at 51s. 6d. three months, and closing sellers quoted 51s. 4d. cash, 51s. 6d. one month, and 51s. 7d. three months. In the afternoon the market was dead idle once again, but the tone continued firm, and sellers of Cleveland warrants named 51s. 4½d. cash, 51s. 6d. one month, and 51s. 7½d. three months. On Tuesday, the day of the State visit to Glasgow of their Majesties King George and Queen Mary, the market was closed. When business was resumed to-day (Wednesday) the tone was strong, values advancing 3½d. per ton in the forenoon, closing with sellers of Cleveland warrants at 51s. 8d. cash, 51s. 9d. one month, and 51s. 10½d. three months. Unfortunately, no doubt due to the disorganisation of all business during the Royal visit, there was nothing doing in the afternoon, prices nominally being 1d. to 1½d. lower. The closing price stood at 51s. 6½d. cash, 51s. 8½d. one month, and 51s. 9d. three months.

Sulphate of Ammonia.—The sulphate of ammonia market keeps fairly steady, with a moderately good demand. The current quotation for prompt lots is 11*l.* 1s. 3d. per ton, Glasgow or Leith.

Scotch Steel Trade.—The idea that any improvement would take place in the Scotch steel trade on this side of the stoppage for the annual Fair Holidays, next week, has now passed away, as the demand has lately been of a miserable nature. The great quantity of foreign material which has been imported, and which is being sold here so cheaply, has hurt the local makers to no little extent, and some of the works have only been able to keep running for something over half-time during the past week or two. Almost all classes of stuff, ship-plates, angles, black sheets, &c., are in poor request, and not only are the various establishments likely to close sooner than usual for the holidays, but the latter are more than likely to be of longer duration than either the masters or the workmen will care for. The export demand is not very heavy, although there is quite a fair amount going through. Prices are unchanged, but where not under official control, sellers are inclined to shade slightly to secure any business offered for immediate despatch.

Malleable-Iron Trade.—The West of Scotland malleable-iron makers are still very badly off for orders, and the approaching holidays will be gladly welcomed by many, as a breathing space is necessary to survey the condition of the trade. The past half-year has proved a very trying period for all connected with the industry, and the worst feature of all is that the outlook is indeed very gloomy.

Scotch Pig-Iron Trade.—The home demand for Scotch pig iron is very dull, owing to the quietness of the local steel and iron trades, and dealing is mostly confined to small lots. The number of furnaces in blast is now seventy, and a goodly proportion of the output is being exported. Hematite continues very dull. Prices are practically unchanged, and the following are the market quotations for makers' (No. 1) iron:—Clyde, 66s.; Calder, Gartsherrie, Summerlee, and Langloan, 66s. 6d. (all shipped at Glasgow); Glengarnock (at Ardrossan), 70s.; Shotts (at Leith), 66s. 6d.; and Carron (at Grangemouth), 67s.

WAR-OFFICE TRIALS OF MOTOR-LORRIES.—The Secretary of the War Office announces that trials of type motor-lorries, under the provisions of the War Department subsidy scheme, will be held in October, 1914, under the same general regulations as for the trials held in May, 1914. Further details regarding these trials will be issued later. Any maker who desires to enter a vehicle of the War Department subsidy type for these trials should notify the Secretary, War Office, as soon as possible.

CANADIAN COAL.—The coal of the Bellz River formation and the Edmonton formation grades between lignites and bituminous. The coal which belongs to the Bellz River horizon is found over an area of about 25,000 square miles; of this area 5000 square miles are estimated to contain 13,000,000,000 tons of coal. The amounts of coal contained in the two provinces of Alberta and Saskatchewan have been estimated at 10,000,000,000 tons and 3,000,000,000 tons respectively. The principal coal-mines within this area in Alberta are near Lethbridge Taber and Lund Creek. The coal of the Edmonton formation is generally lignites, but in the foothills it grades up to bituminous. The total area of workable coal has been estimated at 12,800 square miles, with a probable coal content of 71,000,000,000 tons. The principal coal-mines within this area are near Edmonton. The coal-fields of Saskatchewan are situated in the southern portion of the province, and extend from the boundary of Alberta on the west to the Manitoba boundary on the east. The area underlaid by coal is estimated at 5500 square miles, containing in all about 18,000,000,000 tons of lignite.

NOTES FROM THE SOUTH-WEST.

Cardiff.—The steam-coal trade has not shown any marked change. Tonnage arrivals over the week-end were heavy, and loading operations have proceeded briskly, supplies of coal in most cases being abundant. There was little activity, however, as regards fresh business, both buyers and sellers holding their hands for the present in view of the threats of the marine engineers to hold up trade. The best Admiralty coal has been scarce and firmly held, while other qualities have been plentiful, and somewhat unsteady as regards prices. The best Admiralty large steam-coal has made 20s. 6d. to 21s. 6d.; best secondary qualities 18s. 6d. to 19s. 6d.; other secondary descriptions, 17s. 6d. to 18s.; best bunker smalls, 10s. 9d. to 11s.; and cargo smalls, 7s. 6d. to 8s. 6d. per ton. The best household coal has been quoted at 19s. to 20s.; good households have made 17s. to 18s.; No. 3 Rhondda large has brought 17s. 6d. to 17s. 9d.; and smalls have been quoted at 12s. to 12s. 6d. per ton. No. 2 Rhondda large has realised 8s. 9d. to 9s. 6d., and patent fuel has brought 19s. 6d. to 20s. 6d. per ton. Special foundry coke has been quoted at 25s. to 27s.; good foundry coke at 20s. to 23s.; and furnace ditto, 17s. to 19s. per ton. As regards iron ore, Rubio has made 16s. to 17s. per ton upon a basis of 50 per cent. of iron, and charges, including freight, insurance, &c., to Cardiff or Newport.

Welsh Colliery Deal.—The purchase has been definitely confirmed of the Ynishir Standard Colliery by the United National Collieries, Limited. The transfer is to take place in August. The colliery, which has a mineral area of 500 acres and an output of about 400,000 tons per annum, is acquired, with 800 wagons, mostly 12-tonners.

The Bristol Channel.—The shipments of coal and other fuel from Bristol Channel ports in 1913 amounted to 41,048,791 tons, as compared with 36,296,911 tons in 1912. The shipments from Cardiff were 24,577,083 tons, as compared with 22,420,540 tons; from Newport, 6,134,194 tons, as compared with 5,287,910 tons; from Swansea, 4,499,867 tons, as compared with 3,808,600 tons; and from Port Talbot, 2,515,070 tons, as compared with 2,146,507 tons.

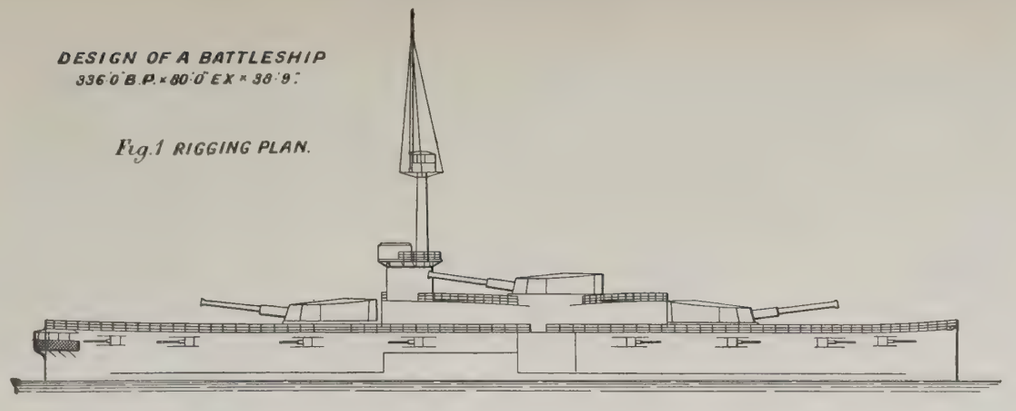
Tonyrefail.—Tonyrefail is growing rapidly. Already a town of recognised importance, Tonyrefail has nearly doubled itself in a few months. This is due to the laying down of a modern plant by the Coppée Company, Limited. The plant includes a full washery, to which coal is brought from the colliery screens. It is tipped by means of two electrically-driven tippers into the unwashed-coal bunker, there to be washed. It is then elevated by means of a bucket-elevator to the screens, where the coal is automatically classified.

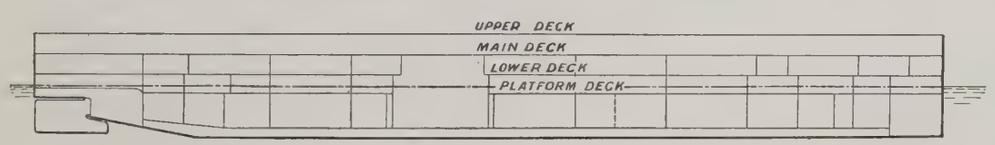
Wireless Progress.—Extensions at the naval wireless station at Horsea Island have been completed, and the poles have been secured. There are three of them, and they are 446 ft. high. They are of Californian pitch pine, and not of steel, as at Poldhu, the Cornwall station.

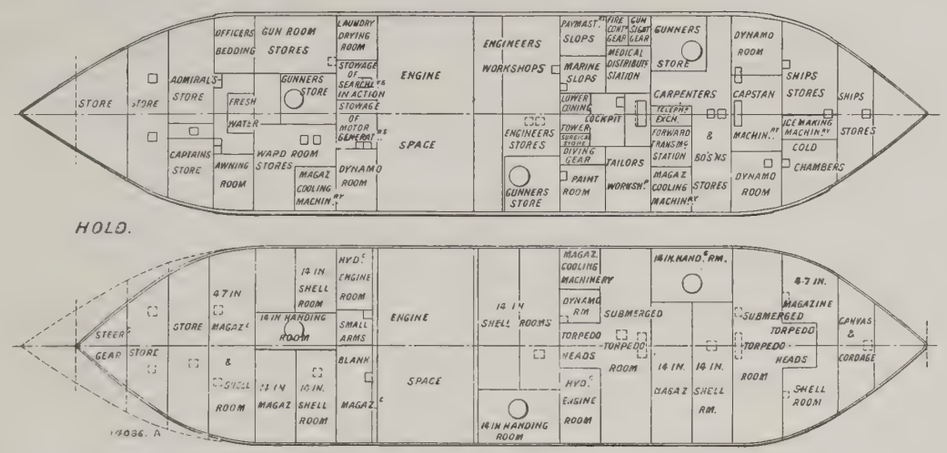
THE COPPER MARKET.—In their monthly report, dated the 1st inst., Messrs. James Lewis and Son state that the market for standard copper has shown little vitality during the past month, sales being limited to about 20,000 tons, prices receding to the extent of 2*l.* 15s. per ton—from 62*l.* 10s. for cash on the 2nd ult. to 59*l.* 15s. on the 26th ult.—recovering to 60*l.* 3s. 9d. on the 29th ult., and closing on the 1st inst. at 61*l.* for cash and 61*l.* 12s. 6d. for three months prompt. For refined copper the demand had been very limited, manufacturers both in Europe and the United States buying only for their immediate requirements. American electrolytic had fallen from 14⅛ to 13½ cents per pound, and from 65*l.* to 62*l.* 15s. per ton c.i.f. The reduction in price had so far failed to attract buyers to any material extent. The average price of standard for the half-year had been 63*l.* 19s. 6d. per ton, against 68*l.* 5s. 9d. for the whole of 1913. American exports for June were advised as 35,182 tons. Imports into Germany for the five months had been 99,788 tons, against 94,920 tons in the same period last year, and the exports 2969 tons, against 4353 tons. Stocks had decreased this year 468 tons, against an increase last year of 7701 tons, making the consumption 97,287 tons, against 82,866 tons—an increase of 14,421 tons, or 17½ per cent.

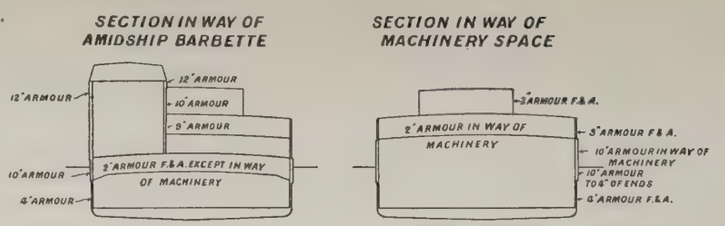
FILTERS AT CLYDEBANK.—By the pressure of a button on a stand erected at Messrs. Beardmore's Works at Clydebank, the King, on the 8th inst., opened the New Paterson Gravity Filtration Plant for purifying the water supply to the Burgh of Clydebank. The filtration plant in question comprises gear for the addition of a trace of coagulant for the removal of the marked discolouration of the water, and a small quantity of lime to correct the natural slightly corrosive tendency of the peaty moorland water; sedimentation tanks for the precipitation of the bulk of the impurities; and open gravity filters for the final purification of the water supply. The latter, eight in number, are the largest mechanical filtration units in the United Kingdom, each having an effective filtering area of 252 sq. ft. An interesting point in connection with the plant is the method of cleansing by compressed air. This operation is performed by first thoroughly agitating the filter-bed for a minute or two with sterilised compressed air at a pressure of about 5 lb. per sq. in. In this way the whole of the bed, even to the remote corners, is loosened and agitated and the impurities, freed from the sand grains, are flushed away into the waste gutter by a reverse current of wash-water. The plant was designed and constructed by the Paterson Engineering Company of London, the consulting engineers being Messrs. Warren and Stuart of Glasgow.

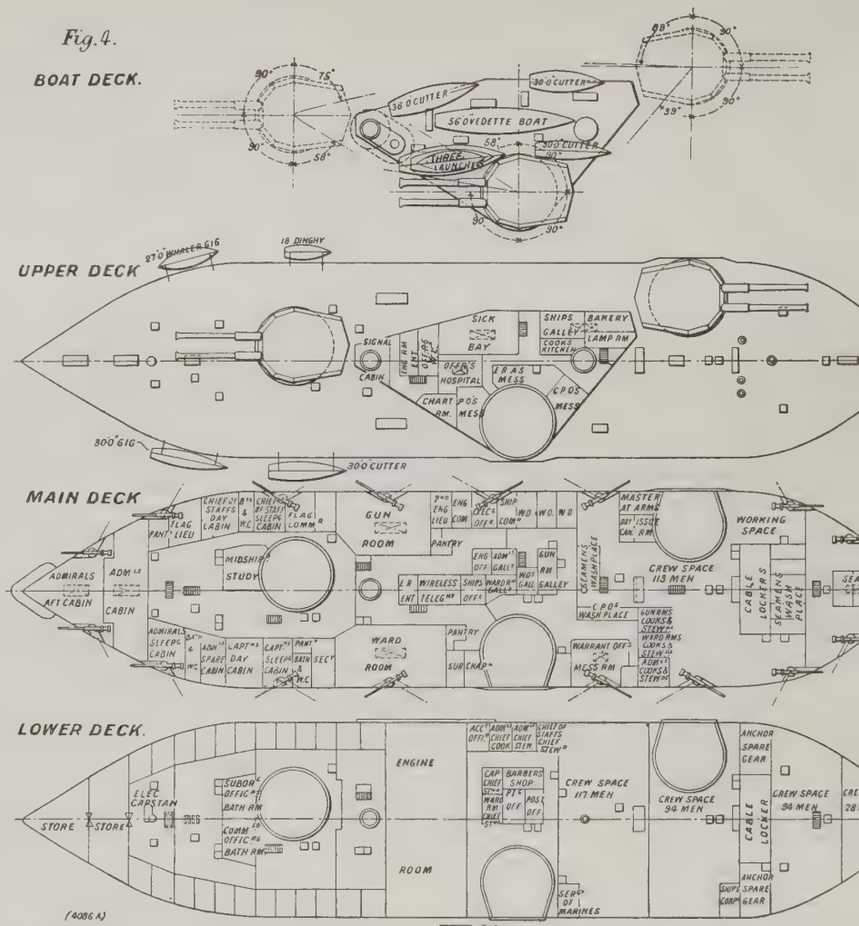
THE PROTECTION OF BATTLESHIPS AGAINST SUBMARINE ATTACK.











ON THE PROTECTION OF BATTLESHIPS AGAINST SUBMARINE ATTACK.*

By Professor Sir JOHN H. BILES, LL.D., D.Sc., Vice-President.

IN a lecture delivered in March last at the Royal Institution, I ventured to remark in relation to the War Navy that the "use of oil and turbines has so reduced the weight of motive power that much higher speeds can be got for the weight that was appropriated in the coal-burning earlier ships. It may be that some of this advantage may be made use of to reduce the size of ships and increase their number. It may be that armour may to some extent be sacrificed, and gun attack be allowed to be more effective in order that some compensation should be available for the effect of torpedo attack. It will thus be seen that the increasing destructive effect of the torpedo brings into the battleship problem the possibility of changes which may once again revolutionise warship design."

The *Times* opened its columns in May to a full discussion of the impending obsolescence of battleships and the coming of the submarine as the dominant fighting ship. In the discussion, it was generally assumed that if the submarine could get within striking distance the battleship must be destroyed. If my memory does not deceive me, it seems that the advent of the spar-torpedo and that of the almost-invisible small torpedo-boat was heralded in the same terms. Some of us have lived to learn the limitations of these cheap methods of destruction, and before too rapidly breaking up our battleships and building no more of them, it may be well to consider what, if any, defence can be given to these poor helpless ships.

In this Institution we have a meeting ground for the statesman, the naval officer, and the ship constructor. The first directs the second, and the third supplies the second with his weapon. We ship constructors are sometimes taken into the confidence of the naval officer, and we try to understand as much as we can of the nature of the onerous duties which he has to perform. We are told that the Navy exists to keep the command of the sea, and that command of the sea is necessary for its freedom. To keep the command it is desirable—some say, necessary—to discover and destroy the enemy's forces. Battleships, cruisers, destroyers, submarines, must all be caught and destroyed or captured, and, equally, all must be capable of resisting destruction or capture. In the two dimensions represented by the surface of the sea, with equal powers of vision, getting within destroying distance is a question of speed, and destruction is a matter of superiority of attack over the defence. The domi-

* Paper read before the Institution of Naval Architects at Newcastle, on July 7, 1914.

nating weapon of attack has been the gun, and the defence against it has been practically all above water, because there its attack has been made. The torpedo-boat and, later, the destroyer, have delivered their main attack below water, but the attacked ship is held to be quite capable of delivering a counter attack by guns above water, which is an adequate reply to the destroyer. The attack of the submarine is wholly below water, and so far the attacked ship has developed no effective reply of its own. The defence against the gun is armour and other guns. The defence against the destroyer's torpedo is the gun, which is quite ineffective against the submarine. The question of interest at the moment is, What defence can the surface ship have against the submarine's torpedo?

There can be only two forms of defence. First, the destruction of the submarine by other vessels, submarine, or others. Second, the protection of the bottom of the surface ships from the effects of under-water attack. The first, the destruction of the submarine, is obviously not the work of a battleship or large cruiser, but must be left to some vessel of the same order of size as the submarine. This destruction must be sought on the surface when the submarine is not submerged, for it seems improbable that a submarine will be able to chase another effectively under the water. In any case, the submarine will be dangerous to the large surface ship until it is destroyed, and, as the means of destruction are not yet certainly to hand, the question of effectively protecting the battleship against under-water attack seems to be deserving of consideration, unless someone is ready with a real reply to the submarine.

One naturally is first met with the question: What about the weight of such protection? The same question can, of course, be asked in the same attitude of mind about any weights used in a ship for the purpose of attack or defence. What about the weight of armour to keep out shot? The thickness and extent of protection ought to be proportioned to the liability to be hit and the damage done when hit. This principle is given effect to when distributing armour protection over a ship to resist gun fire. What is the relative damage done by a 15-in. shell and a 21-in. torpedo, and what is the relative liability to be hit by these projectiles? A distinguished gunner told you in this Institution in April that a modern battleship will be destroyed by gun fire in five minutes after fighting range has been reached. The submarine officer will tell you he can get a torpedo into any ship that he can see and can get within the range of his torpedo. The battleship can hit back at his enemy battleship, but can do nothing by himself against the submarine. What is the liability to be hit in the two cases? Can the submarine find the battleship as surely as the enemy battleship can? In other words, what is the relative liability to be hit by the two methods of attack? This is for the naval officer to tell us, if he can. If the relative liability to be hit is sufficiently great to warrant full consideration of the relative damage, we shall also want to know this. Assuming, as one reasonably may, that very serious damage will be done by the explosion of a torpedo, the next question is, What can be done to prevent or seriously to reduce this damage? Subdivision naturally suggests itself as one means of minimising the effect of this damage, but when all that is possible in this direction has been done, there seems to be no great certainty that a battleship will be still a formidable fighting machine after having received the successful contact explosion of a 21-in. torpedo. Can we do anything in addition to subdivision to preserve the ship for effective fighting purposes?

Armour on the bottom of warships has been proposed by responsible persons. Sir E. J. Reed and General Sir John Crease, R.M.A., during their lives made definite proposals of this character, but they have never been adopted on the outsides of ships, partly for the reason that, previous to the submarine, the torpedo-carrying vessel has been effectively answered by the gun, and partly because the resisting qualities of armour, when submitted to attack by torpedoes, have not been sufficiently well known. The effective advent of the submarine seems to justify a serious consideration of the question of applying armour to the bottoms of ships.

The question of the weight of such armour must be serious, and obviously the addition of such weight cannot be made without some changes and sacrifices. To some it may seem that the readiest way to approach this problem is to clothe the bottom of a 25,000-ton battleship of the latest pattern with armour, and to increase her fullness sufficiently to allow her to carry this armour, letting everything else remain unaltered. The only considerable effect will be to reduce the speed by 2 knots.

This is a direct and simple issue—is the gain in protection worth the loss of speed? This is for the naval officer to decide. The constructor will naturally find difficulties in the way of attaching such armour protection, but he has surmounted difficulties before, and if the naval officer thinks the result worth attaining, the difficulties will doubtless be overcome.

It is not always that the readiest way of approaching a

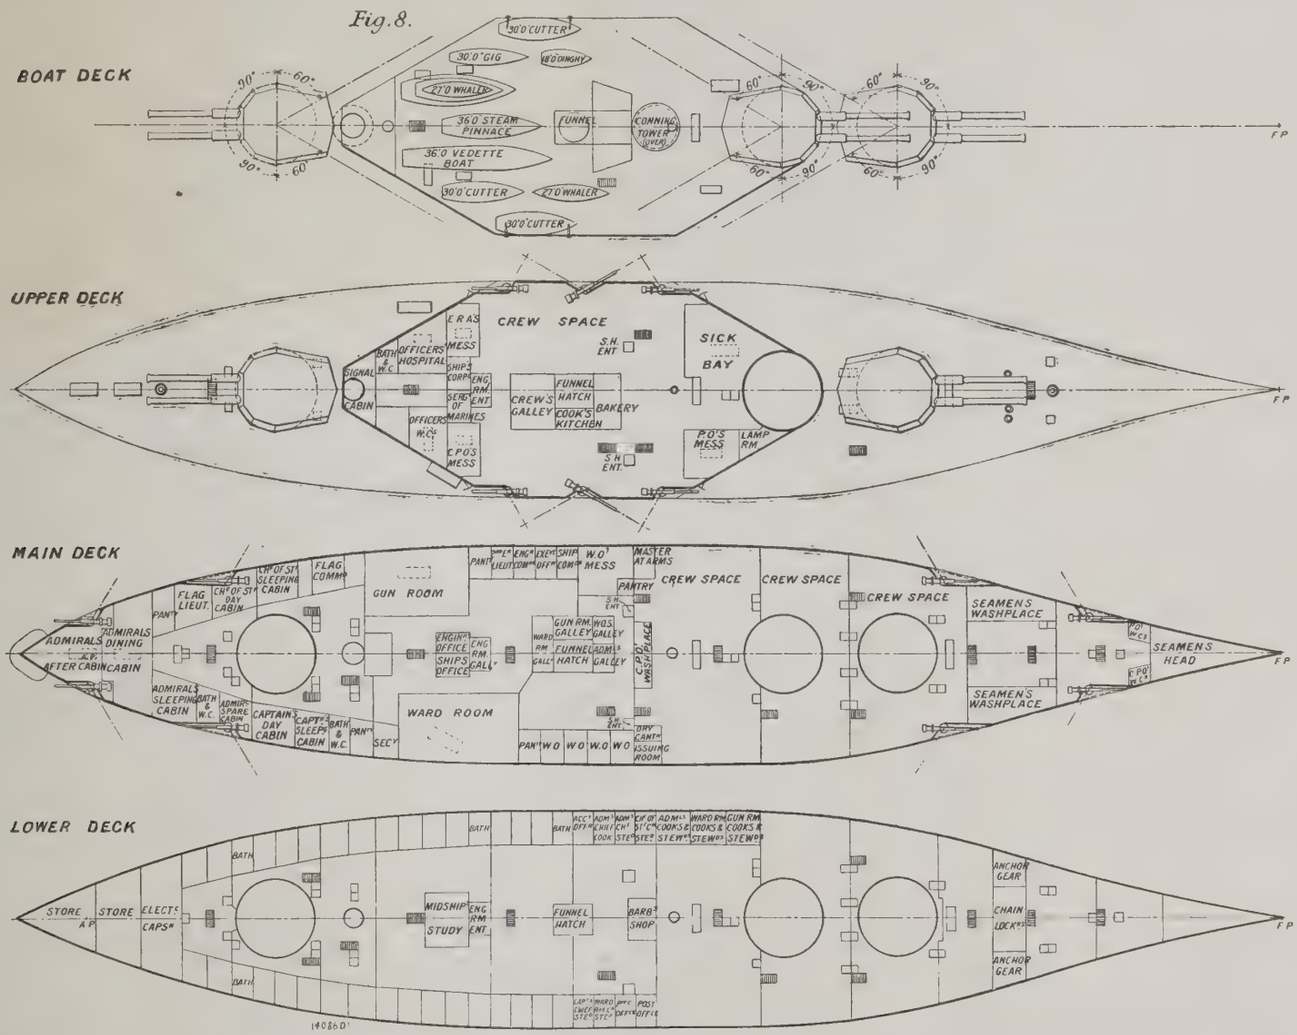
problem gives the best result. One of the characteristics of our latest battleships is that their forms have a low resistance to forward motion. If a form is produced which is better adapted to fitting and carrying armour, though it may involve greater resistance or less speed, it may on the whole be better to adopt such a form. It may be interesting to give an instance or two of the application of this principle. Admiral Sir Reginald Custance has taken us into his confidence about some of his views on the principles which he thinks should underlie naval design. His appreciation of lower speeds and smaller displacements led me to work out what appeared to me to be a limiting case of his views, but combined with these characteristics was associated in this case an armoured protection from torpedo attack. The principal elements of the resulting design (page 65) were as follow :—

Armament	six 14-in., sixteen 5-in.
Thickness of armour :—	
On side at W.L.	5 in.
Above ,, ...	5 ,,
Below ,, ...	4 ,,
On casemate	2 ,,
On barbettes	5 ,,
Thickness of protective deck-plating	2 ,,

This vessel is of about the displacement of the Lord Nelson, which is, when purpose serves, called a Dreadnought. The armament is about the same as the first design, but the armour has been reduced so that it will only keep out 6-in. projectiles. Sir Reginald's view is that none of our ships have armour that will do more, and, that being so, this ship may be considered as sufficiently well armoured above the water-line. All the sections below the water-line are straight, with a circular arc at the end. This form has been adopted to simplify the armour construction of the bottom. It is fully recognised that such a design outrages the convictions of the economists, to whose ranks I want to belong, because ships of such size do not produce the greatest number of guns for a given expenditure. But if we are to be subjected to the ready loss of ships by submarines we may have to be prepared to sacrifice some gun power for our expenditure, and get our recompense in the greater number of ships and guns remaining afloat after the submarine has done its work. It is very rash on the part of a mere naval architect to attempt to reach any conclusion on this difficult question. The facts and figures are placed before this Institution, so that those who are competent to form an opinion may have the opportunity of doing so.

Fig. 8.



Length over all	358 ft.
Length between perpendiculars ...	336 ,,
Breadth, extreme	80 ,,
Draught of water	20 ,,
Displacement in tons	13,000
Speed	10 knots
Armament	six 14 in. ; sixteen 5 in.
Thickness of armour :—	
On side at W.L.	10 in.
Above ,, ...	3 ,,
Below ,, ...	4 ,,
On casemate	2 ,,
On barbettes	12 ,,
Thickness of protective deck-plating	2 ,,

This vessel may be considered as one which could not be expected to find the enemy unless he happened to be bottled up somewhere, but could be less careful than an ordinary battleship about coming out of port on account of the fear of submarines. The size and cost of this vessel should be small enough to satisfy the desires of Admiral Sir Reginald Custance, but it is doubtful whether she would be altogether satisfactory to him.

Anticipating some want of faith in this unusual vessel, a second design was produced having some of the characteristics of the first, but being produced with less disregard of convention. The principal elements are as follow (pages 66 and 67) :—

Length over all...	460 ft.
Length between perpendiculars ...	434 ,,
Breadth, extreme	80 ,,
Draught of water	24 ,,
Displacement in tons	16,000
Speed	18 knots

With a view to enabling those who do not believe in reducing the upper armour of a ship, nor in such a low speed as 18 knots, another design has been considered in which the bottom is armoured, and is of a form similar to the second design, but in which the speed, armour, and armament are of the same order as the Dreadnoughts. Such a vessel could take her place in the First or Second Battle Squadron, and would have armoured protection against torpedoes. The principal elements are as follow :—

Length over all...	600 ft.
Length between perpendiculars ...	570 ,,
Breadth, extreme	91 ,,
Draught of water	28 ft. 6 in.
Displacement in tons...	28,500
Speed	21 knots
Armament	ten 14-in., sixteen 6-in.
Thickness of armour :—	
On side at W.L.	10 in.
Above ,, ...	7 in. and 5 in.
Below ,, ...	4 in.
On casemate	2 ,,
On barbettes	12 ,,
Thickness of protective deck-plating	3 ,,

Briefly, the points for discussion are as follow :—

1. Is 4-in. armour sufficient protection against torpedoes to justify its adoption in battleships of the class of the later Dreadnoughts?

2. Is the submarine menace of sufficient importance to justify the adoption of 4-in. armour protection on the bottom?

3. Is the submarine menace of sufficient importance to justify the building of smaller, slower battleships of, say, 16,000 tons displacement, of 18 knots, having six heavy guns each instead of eight or ten as in the larger ships?

4. Is the method of applying armour to the bottom of sufficient value in itself to justify the adoption of a form of ship which offers greater resistance than the ordinary form?

These are some of the points which suggest themselves for discussion. The form and arrangement of existing ships, though not revealed to us by the Admiralty, may be considered, for this purpose, as sufficiently well known to many to make it unnecessary for a third design to have been embodied in this paper. If it should seem to be desirable further to consider this question of protecting battleships from submarine attack, it will be necessary to determine by experiment the effect of the explosion of a torpedo upon armour attached to a ship. If the submarine menace is judged to be really serious, the necessity for carrying out such experiments seems to be undoubted.

OIL FUEL IN CANADA.—Crude oil is being extensively used as fuel on the Pacific Coast for both steamships and locomotives, and the wide use of the gasoline motor has created a great demand for gasoline. The total imports of petroleum oils, crude and refined, in 1913, were 222,779,293 gallons, valued at 13,230,429 dols. The oil imports included 162,062,201 gallons of crude oil, valued at 5,250,835 dols.; 19,393,627 gallons of refined and illuminating oils, valued at 1,386,440 dols.; and 20,525,170 gallons of gasoline, valued at 4,822,941 dols. The imports of crude and refined petroleum oils in 1912 were 186,787,484 gallons, valued at 11,858,533 dols.

SHIPBUILDING PRACTICE OF THE PRESENT AND FUTURE.*

By Mr. T. G. JOHN, Member.

SHIPBUILDING practice of to-day is the outcome of many forces of varying magnitude, some of which may be said to be at war with one another. Amongst others may be mentioned science, experience, invention, skill, and even prejudice, but most important of all is the fundamental fact that shipbuilding practice results primarily from the necessity of making a profit out of the capital invested. The influence of the different factors at various times fluctuates considerably, but the one which has made most relative progress during recent years is that which may be termed the industrial force, by virtue of which the shipyard workman exercises a generic influence upon methods, efficiency, and cost of production, and incidentally it may be mentioned that this influence is probably stronger in the practice of present-day shipbuilding than in any other engineering industry.

Discussions on the comparative importance of these factors (except the last-named) have in the past filled many pages of the Transactions of this and kindred institutions. The exception has been partly because the subject enters more into the domain of the politician than of the scientist, and discussion of it can, therefore, scarcely be regarded as proper to a scientific institution such as this, although at the same time its relative importance to the industry is admitted to be very large. On the rare occasions when it has been mentioned—as our Transactions will bear witness—it has almost invariably been quoted as a factor more or less antagonistic to scientific progress. At the present time many shipbuilders are more of this opinion than ever, but when viewed in true perspective it must be admitted that its influence upon the ultimate scientific advancement of the industry can be but small, for the simple reason that, were it otherwise, the natural laws of economics would automatically adjust matters. This very debatable side of present-day shipbuilding practice will be referred to again, but this much has been mentioned now because at the present time many of the abilities and energies of our shipbuilders, and of the best of our workmen, are absorbed in solving the labour problems which are of almost daily occurrence, and the scientific advancement of the industry suffers accordingly.

Apart from the historic interest attaching to a study of the improvements which have occurred in shipbuilding practice during recent years, the subject to a certain extent, commands attention by placing various matters in more or less true perspective for forecasting the future.

Shipbuilding is one of our oldest, and still ranks as one of our most important industries, and in its scientific progress we have always taken, and still continue to take, a leading part. Nevertheless, many other spheres of engineering activity have been created since the inception of iron shipbuilding some eighty years ago, and in certain instances have developed so very rapidly that most shipbuilders at times feel a certain amount of regret that shipbuilding science and practice cannot be forced ahead at the same comparative rate of progress. On the other hand, perhaps, no branch of applied science gives rise to problems so varied and difficult as ship construction. Such subjects as structural strength, stability, elasticity, safety in damaged condition, &c., can only be dealt with by the designer with considerable mathematical approximation, and the factor of professional judgment enters very largely into his work. At the same time assumptions have to be made which, from the nature of things, must inevitably differ considerably from the conditions obtaining in actual practice—to say nothing of contingencies created by accidental damage. The finished ship, as built, is the combined result of assumptions, calculations, deductions from observations made on previous ships, together with a comparatively large factor of safety, which is included to give the necessary latitude in the foregoing assumptions and deductions, and particularly to cover the necessary uncertainty which must appertain to all material and to all mechanical operations. It is evident, therefore, that a very considerable amount of interdependence must exist between the shipbuilder and the designer, whose association is perhaps not always as close as it should be. Moreover, methods of manufacture restrict the ambitions of the latter in certain narrow grooves from which he can expand but little, and from this point of view it must be admitted that the improvements in appliances and methods of shipyard practice throughout the shipbuilding world have in recent years scarcely kept pace with the very great expansion of the industry. From the nature of shipbuilding the personal factor attaching to management figures more largely perhaps than in most industries, especially as regards profit earning, but even efficient management necessarily has a limited influence upon the development of shipbuilding practice, besides which, novelties in such practice usually entail a certain amount of risk of failure and consequent financial loss.

Our own shipbuilding industry may roughly be divided into two sections, comprising respectively those establishments which make a practice of building large numbers of medium or small-sized ships of almost standardised pattern, and those which do the better class of work appertaining to large passenger or war vessels. In other countries more variety frequently obtains in each yard, because of the smaller number of establishments. Obviously those of the former section need considerably less variety of equipment than those of the latter, and frequently they achieve good financial results notwithstanding that they use equipment which, for the purpose of the other section, might justly be called crude or inferior. Elaborate equipment being invariably productive of heavy establishment charges, it is not surprising that the large shipyard sometimes meets with difficulty when placing itself in competition for the class of work usually done by the small one. There exists, moreover, a subtle difference in the methods adopted by the respective establishments, but the best quality of work is demanded from all. While, for instance, a tramp steamer or a trawler has to last as long as possible, with more or less indifferent maintenance, on the other hand, a large passenger ship, or warship, becomes obsolete long before it wears out, yet at the same time needs during its comparatively short lifetime a very high standard of structural efficiency. Each establishment, however, whilst retaining its own characteristics, is built up on a strongly competitive basis, and there consequently exists every incentive to utilise whatever economy is available from improved equipment, machinery, and methods.

The Royal Dockyards constitute another class of shipbuilding establishment, but they are only semi-competitive in the above sense, and possess separate characteristics, more especially as regards the system of labour, which incidentally also goes to prove that, could our whole system of labour be entirely recast, a much better one could certainly be evolved. Although in output, cheapness, and quality of work this country still maintains its superiority in face of competition from other nations, and will, we hope, continue to do so, our shipbuilders have had, during recent years, to recognise the fact that several large Continental and American establishments have been extensively developed and equipped with very efficient plant, and that they will in future enter more largely into competition with ourselves. This has had its stimulating effect, but to a certain extent we have suffered handicap in this direction for having been the pioneers of the iron shipbuilding industry, as our establishments were formed and our methods developed when competition was much less severe than it is to-day or is likely to be in the future. It is also scarcely necessary to mention that the close connection which exists between methods and working customs, especially at the present time, limits very considerably the abilities of shipbuilders radically and quickly to alter existing practice.

At the same time it has to be remembered that the equipment and methods of such shipyards abroad have been considerably influenced by the existing local conditions. For instance, where skilled labour is scarce or very highly paid, then every possible labour-saving device is essential, and even in this country local conditions exert considerable influence upon the practice in different yards. Broadly speaking, it may be stated that such developments in our shipyards as have taken place during recent years have been chiefly due to two causes—viz. (1) the increase in dimensions of ships having to be built, with corresponding increase in the size of items of structure; and (2) the ever-persistent desire for economy, coupled with rapidity of production and good quality of work. New methods of manufacture have influenced the developments to a comparatively small extent.

The effect of these causes has been the expenditure of considerable sums of money in three directions, viz.:—

a. Alterations in the topography of the shipyard area.
b. Improvements in lifting and transporting equipment.
c. Improvements in general plant and appliances.

Before studying these in detail, one might mention the difficult position in which the shipbuilder is placed when he has to consider such expenditure owing to want of knowledge of the future requirements he will be called upon to meet, chiefly as regards size of ships and number of contracts. It is in this connection that the capital resources of an establishment tell heaviest, one with large capital, distributed perhaps over several branches of industry, being able to afford to take risks which another cannot. Then, again, the attitude of organised labour frequently deters the shipbuilder from embarking upon a large expenditure in improved plant because of a knowledge that in many cases he would receive a relatively very small return for his outlay, or perhaps none at all. At the same time, no equipment or machinery, however good, will pay for itself if it has only a limited amount of use, and, in any event, depreciation and obsolescence of shipyard equipment and machinery has become so rapid that the up-to-date builder must be prepared, even under present conditions, to scrap the greater portion of his most used machinery after less than fifteen years' service, which period is a continually decreasing one. As the increase in the size of ships is a factor which intimately concerns each of the three previously-mentioned subheads, it is well to remember that, compared with twelve years ago, the number of passenger ships now built per annum which have a tonnage exceeding 10,000 tons has nearly doubled, whilst the average launching weight of large warships during the same period has increased by more than 50 per cent.

ALTERATIONS IN THE TOPOGRAPHY OF THE SHIPYARD AREA.

In examining the development in this direction of most of our large shipbuilding establishments, one frequently gets the impression that, whilst the engineers who originally planned such establishments did so on exceedingly sound manufacturing principles, they at the same time considerably underestimated the requirements of the future. They designed their shipbuilding berths with what they considered to be an ample margin of length and breadth, they arranged their heavy machinery plant on the sound principle that the nearer the machine to the work the less the waste of labour, and then the rest of the yard followed suit. The trouble arises when the margin allowed becomes exhausted and alterations have to be made. This problem has faced many shipbuilders in recent years, and in most cases the solution has been a compromise between heavy capital expenditure and a certain amount of working inefficiency.

To meet present-day possible requirements the builder of the best class of work desires a slipway approaching 1000 ft. long and 100 ft. wide. Many thoughtful people, especially those of other engineering industries, frequently express surprise that the shipbuilder still continues to do most of his work exposed to the weather, but the question of roofed-in *versus* open slipways for large ships (which was a source of considerable debate and much diversity of opinion a decade or two back) seems to have been settled in favour of the open slipway, for at the present time there exists in this country but one roofed-in building in which a modern battleship or large liner can be built, and that one was erected about ten years ago.

At that period the relation which the first cost and maintenance of such a structure bore to its economic advantages was mostly the debatable point, but probably more than anything else the rapid advance made during recent years in the size of ships and the uncertainty of their future dimensions, has confirmed the opinions of most shipbuilders that, in this country, the advantages gained are incommensurate with the large expenditure and risk of obsolescence involved, which opinion may or may not be sound, and, if true now, may be reversed a short time hence, due to causes incidental to labour. In foreign countries also roofed-in slipways are not much in present favour, although in a few instances climatic conditions render them more or less a necessity.

Leaving out the question of cost, the old arguments, as regard advantages and disadvantages of the roofed-in slipway, still hold good—viz., time saved, better quality and cheapness of work, protection of mechanical appliances from the weather, and less expense in cleaning ships, whilst on the other hand there is the reverberating noise, draught, restricted light, &c.

To cover a slipway 1000 ft. long by 100 ft. wide with an iron shed on normal foundations, and having an average clearance from the ground of 140 ft., and, say, 15 ft. at each side, would cost in this country at the present time something like 150,000*l*., which sum does not include overhead lifting equipment, although it includes provision for such. With care such a shed ought to last thirty years, if not scrapped by the march of events before that time; but, assuming such duration of life and interest on capital to be 5 per cent., it appears that the yearly cost, excluding maintenance, will be about 12,500*l*. Whether the benefits are commensurate is, as stated above, open to doubt. For like reasons, except in one or two instances where concrete has perforce to be used as an adjunct to piling to obtain a safe foundation, the average shipbuilder still constructs his ships without the luxury of a concrete or granite slipway, although it involves him in considerably more trouble in fairing them and in carrying out their launching arrangements. In our Admiralty establishments, where all risks are eliminated so far as possible, and financial circumstances are different, such slipways are always used, and the degree of standardisation obtaining in the vessels constructed avoids subsequent disadvantage as regards area of building ground. After launching, *force majeure*, due mostly to their size, still compels the builder in frequent instances to complete his ships at a place more or less distant from the base of his operations. Such necessity is easily conducive to considerable waste of profit, besides entailing many other disadvantages, and with the large ships now obtaining the attendant difficulties are becoming more acute.

IMPROVEMENTS IN LIFTING APPLIANCES.

Slipway Equipments.—In no direction has such a variety of appliances been introduced into shipyards during recent years as in that relating to the overhead equipment of the slipway, and on no subject, perhaps, does more diversity of opinion exist than on the relative economic efficiencies of the various types. Many attempts have been made to calculate such efficiencies from a financial point of view, but it is probable that most estimates are more or less wide of the mark, owing to the problem really being incapable of exact solution; for, whilst such items as first cost, depreciation, and cost of maintenance and operation are fairly easily calculable, on the other hand, such advantages as they give in the direction of time-saving and quality of work are not capable of exact or even fairly approximate computation, and in addition, much depends upon the extent of the use of the appliances during their lifetime, and upon their ability to meet the unknown requirements of the future. Certain it is, however, that the deficiencies of many of those erected during the last decade but one are well realised.

The introduction of such elaborate lifting equipments is of comparatively recent date. Until about twenty years ago the time-honoured mast and derrick system, actuated from suitably placed winches by wire ropes and guys passing through leading blocks, reigned almost supreme, although in a few instances it was supplemented by steam or hand travelling cranes on gantries erected alongside the slipway. It may here be stated that a great proportion of our ships are still constructed under this system, including all warships built in our Royal dockyards. About that time, however, great extensions occurred in the shipbuilding industries of Germany and the United States, and several of our modern equipments had their origin in those countries, where, especially in the last-mentioned one, owing to skilled shipyard labour being able to demand comparatively high wages, every incentive was offered for the introduction of labour-saving devices, and the creation of new establishments furnished the necessary opportunity.

The problem of overhead lifting appliances is a fairly definite one. Briefly stated, material of a great range of weight, shape and size has to be transported to its allotted position in the ship with the minimum of cost

* Paper read before the Institution of Naval Architects at Newcastle-upon-Tyne, July 7, 1914.

and time, and the maximum of handiness, and the equipment should be economical as regards maintenance and working. The arrangement of it should be such that when any portion is delayed, as often happens, the remainder should not be impeded, and up to a certain extent, the greater the number of hooks available for the working squads the greater the efficiency. In view also of uncertainty about the future dimensions of ships, some degree of portability is an added virtue.

The best-known modern systems adopted in this country may be summarised into five types, in all of which each unit is self-contained as regards operative power, viz. :—

(*a*) The American cantilever system, in which two slipways are served by a cantilever crane which travels on a gantry erected between them.

(*b*) The travelling-carriage system, in which a single slipway is served by a number of carriages, either mono- or duo-rail, travelling on the sides or roof of a skeleton structure, and spanning the whole or different parts of the slipway.

(*c*) The wire-cable system, in which the slipway is spanned in the fore-and-aft direction by a number of cableways (usually three or four), which are supported by structures at each end, and which can be given transverse movement, trolleys running on the cables conveying the material.

(*d*) The tower-crane system, in which a number of horizontal jibs supported on independently stable tower structures, fixed or travelling, circumscribe areas over each of the two slipways which they serve.

(*e*) The lattice-built mast-and-derrick system, in which each unit circumscribes a specific area over a particular slipway.

Local variations occur in the details of the systems; but on general principles each system has certain merits and demerits, which may roughly be stated as follows:—

AMERICAN CANTILEVER SYSTEM.—*Merits:* Large range of lifting capacity at different radii: large area covered by a single unit; ability to pick up practically all loads from the heads or sides of slipway; ease of control.

Demerits: Heavy first cost; stability being dependent on weight, the travelling portion must be extremely heavy in comparison with the average weight lifted, thereby entailing large wasted expenditure of power; restricted access given to one side of each slipway at the midship portion; large amount of structure involved, much of which is difficult of access, thereby enhancing cost of maintenance; large area of yard occupied by gantries; inability to work in strong winds; operator far away from the work; non-portability, poor facilities for handling material and hydraulic riveting tools and inability to deal with sufficient loads in a stated time to anything like adequately meet the needs of two large vessels building under modern conditions.

TRAVELLING-CARRIAGE SYSTEM.—*Merits:* Large number of hooks available for handling, transporting and riveting operations, which number can, to meet exigencies, be quite easily increased even up to fifteen or sixteen per berth; ability to work in strong winds; quick transport; carriages can combine for heavy loads; operators have good view of their work.

Demerits: Very great first cost; installation limits expansion of breadth of slipway, and involves disadvantages as regards area of building ground; limited ability to pick up material from head or sides of slipway; expensive in maintenance and a certain amount of interference occurs with the carriages.

WIRE-CABLEWAY SYSTEM.—*Merits:* Comparatively low first cost; rapidity of conveyance; ability to take up loads from head of slipway; small ground area occupied by supports; small power absorbed; ability to work in strong winds; trolleys can combine to a certain extent for heavy loads.

Demerits: Very limited number of hooks available for handling material, &c., and these are not suitable for riveting machines; difficult to arrange for heavy loads; limited ability to pick up loads at sides of slipway; troublesome questions of tension and sag in cables.

TOWER-CRANE SYSTEM.—*Merits:* Comparatively low first cost; rapidity of conveyance; small power absorbed; ability to work in strong winds; breakdown of a unit has small effect; system lends itself to extension of length of ship served; semi-portability.

Demerits: Only certain cranes can take up loads from head of slipway; maintenance expenses somewhat heavy; operators far away from their work.

LATTICE-BUILT MAST-AND-DERRICK SYSTEM.—*Merits:* Small area of yard occupied; large number of hooks available for handling material and riveting machines; ability to work in strong winds; considerable portability, giving advantage of altering lines and areas of slipways.

Demerits: Obstruction caused by multiplicity of stays, with consequent difficulty in co-ordinating with any other existing devices; non-ability to pick up material from head of slipway; limited area of ship covered, involving a certain amount of laborious handling of material.

In selecting his equipment each shipbuilder, of course, will have considered the subject from the point of view of his own peculiar needs, and, in addition to other factors, will probably have had to contemplate the serious disorganisation of his work whilst the installation is being made.

Considered from the financial aspect, the cost of maintenance and working of most of the systems is, under normal conditions, comparatively a small item when judged by the amount of work they perform. Such costs necessarily vary according to temporary and local conditions, but on the other hand comparisons in capital costs per annum are fairly definite, and the following table has been compiled on the assumption that the life of the equipment is twenty years and interest on capital is taken at 5 per cent. The first cost is estimated on present-day prices, and the foundations and conditions of erection are assumed to be normal. Studied in conjunction with their relative merits and demerits, however, it seems safe to say that the efficiencies of the respective systems cannot be in the direct ratio of their costs, and it is more or less unsafe to say anything further.

Comparison of Present-Day Costs of Overhead Equipments Designed to Serve Efficiently a Slipway 1000 *Ft. Long by* 100 *Ft. Wide.*

Capacity at Maximum Outreach in each System is 5 Tons.

System.	Number of Hooks Available.	Total Cost per Slipway.	Capital Cost per Annum.
		£	£
American cantilever ..	½ to 1*	15,000	1500
Travelling carriage ..	15	95,000	9500
Wire cableway	4	10,000	1000
Tower crane	3 to 6*	13,200	1320
Lattice-built mast and derrick	16	24,600	2400

* Each hook is available for two slipways.

At the present time shipbuilding opinion is largely in favour of the tower-crane system, as may be deduced from the fact that during the past year or two a number of these have been installed in four large establishments in this country—viz., Messrs. Harland and Wolff, Limited, Belfast; Messrs. Workman, Clark and Co., Limited, Belfast; Messrs. Sir W. G. Armstrong, Whitworth and Co., Limited, Newcastle-on-Tyne; and Messrs. Vickers, Limited, Barrow-in-Furness, the cranes having in each case been designed and constructed by Messrs. Sir William Arrol and Co., Limited. In foreign countries, besides in Germany, they have been installed in recent years in shipbuilding yards at Ferrol, Havre, Dunkerque, Genoa, Schiedam, and possibly in others. All are, of course, electrically operated. Opinion varies as to the most desirable lifting capacity, and as to the proportionate area of slipway which should be covered. As regards the former, it is interesting to note that plates weighing up to 8 tons are not uncommon in ships now under construction, and even this weight is frequently very much exceeded, whilst in moderate-sized vessels built on the Isherwood system items of framing weighing up to 10 tons have often to be dealt with.

A brief description of the installation now being erected in the shipyard of Messrs. Vickers at Barrow-in-Furness may be interesting.

The arrangement is shown diagrammatically in Fig. 1, page 70, and consists of two parallel rows of fixed cranes, containing five in the longer row and four in the shorter, with a clear width of 213 ft. between them, in this fashion serving four slipways, whose respective lengths are approximately 900 ft., 830 ft., 770 ft., and 720 ft., with possibilities of extension in each case. The crane at the lower end of each row is placed so that bulky materials may be lifted out of a barge afloat in the channel, thus obviating the congestion which inevitably occurs when cumbersome items have to be transported through the yard. Each crane has a jib of 120 ft. radius, seven of them are capable of lifting loads of 5 tons at the extreme radius; whilst the other two (the second from the forward end of each row) are designed to lift 15 tons at the extreme radius, and all will lift double those respective loads at half radius. The cranes have been given a large amount of overlap, and the heavy ones provided both to meet the increasing variety of heavy lifts now dealt with in modern big ships and in view of possible future requirements. With the two heavier cranes, boilers and heavy items of propelling machinery, &c., can be shipped on the slipway, and the great advantages accruing therefrom realised. The lowest jib of the whole installation is 95 ft. from the ground, and the highest 156 ft., thus providing a liberal margin for increase in height of ships beyond present-day requirements. The structural design of one of the 5-ton cranes is shown in Fig. 2, page 70. Owing to the units being a considerable advance in size and power from anything of the sort previously constructed, new difficulties were, of course, met with, both in design and working; for instance, owing to the comparatively large moment of momentum of the revolving structure with its load, the controlling arrangements had to be very carefully devised, and the limited experience already gained has shown the advantages to be realised by balancing them against wind pressure, wind sails, as shown in the diagram, having been added.

It will be noticed that the bases of the cranes have been arranged to permit of bulky loads, such as boilers, being conveyed to positions convenient for lifting on board ships.

Finishing-Berth Crane Equipment.—The equipment of the modern afloat berth presents a problem altogether different from that of the slipway. The small weight requiring to be placed in positions far apart still predominates, but the comparatively few heavy items are of ever-increasing weight, so that the modern large crane for such purpose needs a capacity of something near 200 tons, and this leaves very little margin for the future. It is significant that two of the most recently erected of such cranes have a working capacity of 250 tons.

The march of progress in this direction has been so very rapid that it is surprising to reflect that it is only eight years since the last heavy sheerlegs were erected to serve a finishing berth in this country, although at the present time such a type is regarded as entirely obsolete, giving, as it does, slow and very limited area of service, and necessitating frequent moving of the vessel. Owing to the concentration of pressures, the foundations are also often difficult to provide. Derrick cranes, actuated by hydraulic or electric power, have been installed in several instances at home and abroad, but modern opinion is largely in favour of the types known as the "Hammerhead" or "Giant" revolving cranes, electrically operated.

The problem of the light load at such berths has not yet been completely solved, but it has been partially met by subsidiary hoists working on the structures of the forementioned heavy cranes, by travelling-cranes with long outreach on the wharves, and by floating-cranes; and it is interesting to note that the maximum capacities of the two former types have recently increased from about 10 tons to the vicinity of 30 tons, the latter now being generally regarded as the most desirable range for subsidiary service of large vessels.

Other Transport Arrangements.—The remaining transport arrangements of modern shipyards call for little mention, as they are proceeding on fairly well-established principles. In the machine-sheds new problems in certain instances have had to be faced, both because of much heavier items of material having to be dealt with, and because more expeditious handling has become necessary. Overhead travellers have not in the past been as common as they might have been in such sheds, but in new ones they are in most cases being installed. As, however, in the first instance the shed usually needs to be designed, both as regards structure and head-room, to receive such an equipment, it is not often possible to make the improvement in existing ones. Overhead railways are in operation to a certain extent, and this system seems suitable for much more consideration from designers, with a view to further adoption.

IMPROVEMENTS IN GENERAL PLANT AND APPLIANCES.

As previously stated, these have been comparatively few, such as have occurred being principally due to such influences as a desire for increased output, reasons of economy, and new methods. There is no doubt that in this section great opportunities still exist for inventors and manufacturers of machine-tools and plant. As bearing evidence to the increased demands during recent years for the inclusion of exceptionally long and broad plates in ship construction, may be mentioned the difficulties experienced by builders with their bending and rolling machinery. Nine years ago bending-rolls capable of working a plate up to 30 ft. long by 2 in. thick when cold were generally considered sufficient to meet future needs. The next seven years witnessed the necessity of dealing with plates up to 40 ft. long by 2 in. thick, and at the present date rolls of even this capacity are proving inadequate to meet the demands of the ship-designer, plates having length and breadth up to 48 ft. and 11 ft. respectively being incorporated in ships now under construction.

The introduction of pneumatic tools some seventeen years ago for drilling, caulking, chipping and riveting, has led to their use on such an extended scale that it is difficult to imagine the difficulties which would arise in present-day shipbuilding if it were suddenly deprived of their assistance. Here, again, the economic results achieved by their adoption are not strictly capable of computation, for whilst the output per man using these tools is increased on an average about threefold, the outlay involved and costs of depreciation and maintenance of such tools is considerable; power has to be generated and by virtue of piecework agreements many of the benefits pass to the workman, by enabling him to earn higher wages, the deductions from which, for his increased output, vary in this country in the vicinity of 40 per cent. In this connection, however, it has to be remembered that the average workman is not so much concerned with the relative rates of pay as with his total earnings, and if pneumatic tools had not been introduced it is quite probable that the hand-work rates would have increased much more than they have done.

The chief advantages to the shipbuilder using such tools are in the greater output and better quality of work which they give him; and although, as stated, their financial effect is of a complex nature and not exactly calculable, it is not inconsiderable.

For the operations of drilling, reaming, caulking, and cutting, the utility of pneumatic tools is unquestionable, although the oxy-acetylene tool is coming much into use for the latter operation, but the extent to which pneumatic riveting is adopted varies considerably in different establishments in this country and abroad. Professional opinion, after seventeen years' experience, is still far from unanimous on the subject of pneumatic riveting, but most shipbuilders agree that, given efficient "holding up," pneumatic riveting, in the hands of a moderately-skilful workman, is at least equal in quality to and frequently excels hand-work, whilst at the same time the output per man is considerably increased. Its adoption in most yards is, in fact, limited by the sufficiency or otherwise of the power pressure available, by the willingness of the workmen to operate it, and by the extent to which holding-up appliances have been devised or are applicable. An added virtue possessed by all pneumatic tools lies in the fact that in the hands of an otherwise inferior workman they can be made to give quite a good quality of work, which in times of scarcity of labour would otherwise be lost. Hydraulic power has for a long time been used to a certain extent in shipyards in this country for riveting, and, until recently, considerably more so than in most foreign countries. Hydraulic riveting is nearly always of the best possible quality, and for certain important items of structure is almost a necessity, so that in every way its extension is much to be desired in ship construction.

The greatest difficulty in the way of extension of hydraulic riveting is due to the inordinate weight and size of the portable plant connected with it; for instance, a 6-ft. gap scissors machine, capable of closing 1¼-in. diameter mild-steel rivets, weighs something like 2¾ tons.

On this account special appliances, and often much labour, are needed to manipulate such tools, the work as a result frequently being slow and expensive. The hydraulic riveter in use to-day is in many respects a crude machine, and seems capable of considerable improvement in design for use in shipbuilding. It ought not, for instance, to be a necessity for the ship-designer, as is often the case, to have to narrow his plates so as to permit of hydraulic riveting by bringing the riveting-machine within manipulative weight and dimensions.

In connection with power riveting, it is generally realised that comparative results of efficiency of riveting taken from test specimens are often apt to be misleading. Machine riveting throughout a ship, whether done by pneumatic or hydraulic power, invariably approximates more closely to the selected test pieces than does hand work, owing to the personal factor of the average ability of the workman.

Other than for riveting, the only direction in which the use of hydraulic power in shipyards has been appreciably extended in recent years has been in connection with the manufacture of such items as plate collars, knees, brackets, &c., by die-stamping, besides which many fittings, previously made of forgings or castings, have been replaced by much less expensive stampings, notably pillar heads and feet, bollards, wells in flats and bottoms, &c.

Although in present-day shipbuilding each form of operative power acts more or less efficiently in its own sphere of usefulness, it may not be out of place to mention the great economy which would result if all these could be transmitted and utilised in one form. Multiplication of plant for generating power and its distribution over wide areas is an item of considerable expense in a modern shipyard, and anything in the nature of simplification is much to be desired. Of the prime energy systems, electricity seems the most suitable for unification, and whilst such an ideal is, perhaps, too much to hope for at present, it is not without interest that one can, even now, purchase an electrically-operated riveting hammer or an hydraulic riveter actuated by a self-contained electrically-driven pump, the latter being neither exceptionally bulky nor heavy.

Space forbids more than the mention of many minor appliances and machine tools which have recently been introduced into shipyard plant, such as friction saws, oil furnaces, &c., many of which have been in use for some time in other industries, but have either only lately been adapted to meet the shipbuilder's requirements, or else the requirements were not sufficiently pressing to warrant their adoption. The development of producer-gas plant also in recent years has given the shipbuilder opportunity of utilising it for his purposes, and the gas-furnace, with its attendant advantages of uniform heating, is now in common use in many shipyards.

As exemplifying improvements which are not altogether of the nature of plant, one may mention those in the direction of templating, &c., the constituent items of a ship's structure, and in this connection the exact relationship which the operations of the mould-loft bear to the subsequent work of the plating department remain more or less indefinite. It can readily be understood that in passing from the mould-loft, where all operations are dependent upon exactitude, to the different parts of the structure of a ship manufactured by workmen possessing varying ability, much opportunity occurs for wasted effort and poor execution. The template and batten system, emanating from the mould-loft with a maximum amount of standardisation incorporated, has been extensively used of late to eliminate such defects as much as possible. The system, however, to be successfully worked necessitates a considerable amount of co-operation on the part of the individual workman, together with keen supervision and frequent checking, even of the template, failing which, a mistake, occurring perhaps in the early stages of the work, is not discovered until a considerable amount of structure is involved, and is more or less costly to rectify. Different establishments work this system to a varying extent, but looked upon scientifically it is an excellent method, and its extension is much to be desired. Because of the above-mentioned reasons, however, "board work" continues to be used to a considerable extent, and although the method is slower, on the other hand the accuracy of the resulting work in most cases is more assured. Speaking generally, the factors which decide the method adopted are the facilities of the establishment, the price list, the urgency of the work, its desired extent of accuracy, and the individual ability of the workman to whom the work is entrusted.

In the same connection, the subject of standardising as much as possible the plate and angle-bar constituents of a ship's structure has been receiving some attention from shipbuilders, and the advantages of doing so, from a manufacturing point of view, are very evident. In the structure of floating docks the practice has for some time been extensively adopted, whilst it is also used to a certain extent in merchant and passenger ship work. In large warships, on the other hand, it is as yet almost non-existent.

Launching practice as applied to large and heavy vessels has undergone some modification in recent years. The time-honoured device which has been perpetuated since the days of the wooden shipbuilding industry, whereby the ship was released by the mechanical removal of two or more dogshores, has now given way to the more positive method of simultaneously releasing a number of triggers by electric or hydraulic power. The former system, however, still obtains in our Royal Dockyards, and in a few private establishments, although the much greater security and safety of the trigger methods seem more than sufficient to warrant their adoption. Another small detail regarding launching practice, which is worthy of mention, is the increasing custom in recent years of incorporating a horizontal layer of soft wood below the forward poppets in heavy vessels, with the object of distributing over as large an area as possible the pressure created when the stern lifts. Shipbuilding opinion is not unanimous as regards this practice, but it is prevalent, and has a tendency to become more so.

Regarding Future Developments.

One treads on very uncertain ground when approaching the future of a great industry like shipbuilding, and one has to bear in mind that the builder who is in advance of his times is penalised nearly as much as the one who is behind them. At the same time the desirability of intelligent realisation and anticipation by the shipbuilder of

the future needs of the industry requires no emphasis. The very fact of the existence of so many imperfections in shipbuilding practice is a sufficient guarantee that in process of time some, if not all of them, will be remedied, to the benefit of the shipyard and the ships.

Several instances have already been mentioned in previous parts of this paper where room exists for improvements upon present practice, and, of course, certain desiderata are, and always will be, present in the economics of the shipbuilding industry; for example, inexpensiveness and efficiency of materials, labour and methods, if not separately, then in combination.

The developments of the distant future are, naturally, too chimerical safely to debate, and obviously are dependent upon those of the near future. As regards the latter, certain presumptions are fairly positive—for instance, that the size of certain types of ships will continue to expand, and that economic competition will increase in severity, and at the same time become more world-wide. It is impossible to contemplate the future development of an industry such as this without appreciating how largely labour influences at home and abroad will certainly exert their pressure. It is unfortunate that trade unionism in shipbuilding practice, as in certain other industries in this country, has developed along such lines as to render the task of bringing the interests of the workman into line with those of the employer an almost impossible one. Notwithstanding much consideration having been given to this subject, and the trial and failure of the principle of co-partnership, the situation remains, to say the least, without tangible improvement. Whether and when any fixed basis for permanent settlement will be arrived at are highly speculative questions. But, on the other hand, two things are fairly certain: first, that certain sections of the shipbuilding industry in this country have grown up on such very different lines from most other engineering industries that the high degree of economical efficiency attained by the individual producer in the latter is not likely, for some time, at least, to be achieved in the former, not necessarily because of any marked difference in the efficiency of the average workman, but because of the fact that shipbuilding operations are not generally adaptable to highly standardised repetitive methods; and secondly, that in common with all skilled workers, the shippard workman will, as time advances, and his education increases, become progressively averse to heavy sustained manual labour. For the immediate future, therefore, the industry will have to place most dependence upon the inventor of more efficient methods and appliances for its continued progress. Incidentally, development along such lines should go far to remove the embarrassment caused both to trade unions and employers by the presence, at busy times like the present, of the inferior workman. Again, it is scarcely reasonable to assume that the steel ship of to-day—reached after development extending through less than a century —will be the prototype as regards structural details of the ship of a century heuce, and it is equally certain that the weakness of the ship of to-day lies mostly in its smaller structural details. Much of this is due to the want of improved processes—the resemblance which the great mass of structural details of our latest ships bear to those of Brunel's Great Eastern, besides bearing testimony to the genius of its designer, goes to prove this contention—and it can therefore be expected that many efforts in the future will go towards the improvements of structural details and of the methods by which such details are manufactured.

It is remarkable, for instance, to what an extent the rivet remains a fundamental unit in ship construction. It is certainly a very positive method of connection; but, owing to its employment, there exists a multitude of small added weights due to laps, butt-straps, angle-bars, doublings, corner-pieces, &c., and at the same time there is created a non-uniformity of strength and elasticity throughout the entire structure. Then again, very casual study of a typical water-tight bulkhead or flat in present-day shipbuilding serves to make one realise the necessary crudity of its design and construction, in association with the vital functions which it has to perform. The material is badly disposed for resisting the stresses to which it may be subjected, there is an absence of uniformity of strength, and when stressed it leaks and becomes more or less inefficient when only a very small proportion of the ultimate strength of its material is developed. These statements are made for the purpose of indicating the great need which exists in shipbuilding practice for the adoption of a reliable fusion process for connecting structural material, if only to reinforce the efficiency of the riveted joint. It is a far step from this to the abolition of the rivet itself in general construction work, but it is not so far to its abolition in such places as joints of bulkheads or flats.

It is not difficult to see that non-uniformity of strength is also principally due to the riveted formation. If the joints could be welded, the natural sequence would be for the ductility of the material to be more utilised, by adopting flanging or perhaps corrugation of varying intensity, to give the necessary uniformity of strength desired to withstand water pressure, or sustain loads, the specific area treated by such means depending, of course, upon its position in the ship and upon its relative functions. Incidentally, it is also remarkable to what small degree the ductility of steel is taken advantage of in ship construction. Sheet-iron and sheet-steel work have made such great progress in the industrial world during recent years that they afford many latent suggestions for ship construction on a bigger scale. It is not impossible that certain joints of the thinner flats, &c., in the future, may be made by a combination of the beaded joint with surface welding, and perhaps even the shell or deck joints may be made by giving the edges such configuration that they acquire the necessary strength when finally welded together, if such could not be obtained by the simple butt weld alone.

TABLE I.—RESULTS OF TESTS CARRIED OUT ON SAMPLES OF MILD STEEL WELDED ELECTRICALLY BY THE "QUAZARC" PROCESS.

Tensile Strength of Steel, 26 to 30 Tons per Sq. In.

No. of Sample.	Description of Joint in Test-Piece.	Dimensions of Section in Inches.	Area, Sq. In.	Tons on Sq. In.	Elongation per Cent. in 8 In.	Nature of Test.	Remarks.	Sketch of Welded Joint.
A 1	Butt weld	2×.5	1	25	6.5	Tensile	Clean fracture through weld	
A 2	Do.	2×.5	1	22	3	,,	Do. do.	
A 3	Do.	2×.5	1	—	—	Bending	Bent through 115 deg. over a radius of $\frac{5}{8}$ in. — broke through weld.	
A 4	Do.	2×.5	1	—	—	,,	Bent through 180 deg. over a radius of $1\frac{3}{8}$ in.—without fracture.	
B 1	Plates overlapped $\frac{1}{8}$ in., and welded on each side ..	2×.5	1	17.2	5	Tensile	Clean fracture at weld.	
B 2		2×.5	1	21.8	7	,,	Do. do.	
B 3	Do. Do.	2×.5	1	—	—	Bending	Bent through 57 deg. over $\frac{3}{4}$ in. radius without fracture	
B 4	Do. Do.	2×.5	1	—	—	,,	Bent through 180 deg. over $2\frac{1}{4}$ in. radius without fracture.	
C 1	Flat bar welded on, and then machined off before testing sample	2×.5	1	25.5	22.5	Tensile	Fractured outside the locality where flat bar was welded on.	
C 2		2×.5	1	24.5	23	,,	Do. Do.	
C 3		2×.5	1	—	—	Bending	Bent double between welds over $\frac{5}{8}$ in. radius without fracture.	
C 4	Do. Do.	2× 5	1	—	—	,,	Bent double at weld over $\frac{5}{8}$ in. radius, very slight fracture showing at part where flat bar had been welded.	
D 1	Longitudinal butt weld	2×.4	.8	28.2	18	Tensile	Clean fracture across weld.	
D 2	Do. do.	2×.42	.84	29.2	21	,,	Very minute signs of fracture along whole length of weld.	
D 3	Do. do.	2×.4	.8	—	—	Bending	Bent double over $1\frac{1}{2}$ in. radius—slight fracture at welded part.	
H 1	Two 7-in. × $\frac{3}{8}$-in. bars welded together to form angle	—	—	—	—	,,	Points of angle closed in—no fracture.	
H 2		—	—	—	—	,,	Points of angle opened out—fracture at weld commencing.	
H 3	Do. do.	—	—	—	—	Not tested		
F 1	Flanged plate welded to angle bar at heel and toe	4.5×.5	—	Breaking stress 43	4	Tensile	Clean fracture along weld.	
F 3		4.5×.5	—	39	3	Do.	Do. do.	
F 5	Flanged plate riveted to angle-bar	$5\frac{3}{8}$ ×.5	—	18 5	—	Do.	Three $\frac{3}{4}$-in. countersunk rivets — rivets pulled through holes	
K	Plates lapped and single-riveted —one seam welded	—	—	—	—	Bending	Bent through 35 deg. at joint —no fracture at weld	

(4081 B)

Until recently, also electric arc welding when used on detail work has given indifferent results, presumably owing to the oxygen of the atmosphere combining with the carbon in the steel, resulting in the disintegration of the latter and its consequent evils. A patented process lately evolved and passing under the name of the "Quazarc" process is engaging the attention of some shipbuilders at the present time, and promises better results. It may be described as an electric fusion process, in which the weld is obtained by the addition of molten metal. It has been the subject of recent experiments at the shipyard of Messrs. Vickers, and the tabulated results of some interesting experiments on test-pieces treated with it are set out in Table I. Unfortunately, this is an example of a process in which the result of work done on test-pieces has a limited value for gauging its applicability on a large scale to ship construction. At the same time, the experiments, so far as they have gone, and allowing for want of experience on the part of the operators, showed the ease of operation, the comparative cheapness of the process, and the efficiency of the results.

As might have been expected, the elasticity in the region of the weld is somewhat reduced, and, although not tested, it is only reasonable to assume that the resistance offered to fatigue stresses by a structure so treated would also be reduced, but probably not to a prejudicial extent. As in all electric arc-welding processes, both these defects could be improved, if not removed altogether by reheating and working the junction. This latter finishing operation would not necessarily be impossible to perform in ship construction, but the margin of safety without it would doubtless, in most cases, be sufficiently large to enable the deficiencies to be tolerated. On the other hand, the resistance to influences creating corrosion should be considerably increased by treatment similar to the "Quazarc" process.

The subject of the applicability of such a process to ship construction is extremely interesting, and, although much experience will have to be gained and many difficulties overcome before its adoption on any large scale could be entertained, it is only reasonable to assume, in the light of past and present knowledge, that sooner or later a process of this nature will exert a considerable influence over future shipbuilding practice.

In this relation it is not even certain that steel, at least as we know it, will be the material to be used in ships of the more or less distant future, although because of the abundance of iron in nature and its consequent cheapness, it is very likely that iron will be its basic element. The science of metallurgy has made such rapid strides in recent years that it is reasonable to assume that sooner or later a metal may be evolved possessing all the good characteristics of present-day steel in an accentuated form, and in addition be less liable to corrosion. The problem in this direction may perhaps be stated to be chiefly one of cost. As an example of such possibilities, although of a slightly different nature, might be mentioned duralumin, an alloy of aluminium, which can be made to possess most of the good characteristics of steel (except weldability) in an enhanced degree, while being only about one-third as heavy as that material. Unfortunately, duralumin, although meeting a definite need in engineering and in certain other industries, is at present prohibitive for ship construction on a large scale on account of its cost, being for shipbuilding purposes about twelve times dearer than steel. Sufficient, however, has been said to indicate the scope which exists in shipbuilding practice for the scientist, the inventor, and perhaps the philanthropist, and whilst waiting for the success of their efforts, the shipbuilder can but proceed in the direction of eliminating wasted effort, perfecting such details as he can, and taking full advantage of standardisation and repetitive work to reap whatever economy may result.

In conclusion, the author desires to express thanks to the directors of Messrs. Vickers, Limited, for permission to quote various details; to Messrs. Sir William Arrol and Co., Limited, for information supplied by them, and to several professional friends for helpful criticism and assistance rendered in the compilation of this paper.

BALDWIN LOCOMOTIVES. — During the last eighteen months the Baldwin Locomotive Works Company has been obliged to reduce the number of its employees from 19,500 to 8200. The hours of the day men have also been cut down from 55 to 40 per week, while those of night shifts have been reduced from 65 to 39.

OIL IN AUSTRALIA.—Considerable attention is being paid to prospecting for oil deposits in South Australia, and to radioactive ores. Licenses to search for oil have been granted, and bores are being put down in the southern part of Kangaroo Island, the south-west of Eyre Peninsula, and in the south-east. The Government has offered a bonus of 5000*l.* for the first 100,000 gallons of crude petroleum containing not less than 90 per cent. of products obtainable by distillation.

COLONIAL AND FOREIGN ENGINEERING PROJECTS.

WE give below a few data on several colonial and foreign engineering projects taken from the *Board of Trade Journal*. Further information concerning these projects can be obtained from the Commercial Intelligence Branch, Board of Trade, 73, Basinghall-street, London, E.C.

Tasmania: The Imperial Trade Correspondent at Hobart has forwarded an extract from the local Press stating that the Launceston Municipal Council has adopted recommendations to extend and duplicate the existing tramway lines at a cost of 60,000*l*.

Egypt: The Egyptian *Journal Officiel* notifies that tenders are invited by the Municipality of Alexandria for the construction of a drainage system for that town. The work comprises (1) the construction of a general system of sewers, (2) the erection of a pumping-station at Kaïd Bey, and (3) the construction of a main outfall into the sea. Tenders may be made for the whole or for part of the work. Sealed tenders will be received, up to noon on December 8, by M. le Président de la Commission Municipale d'Alexandrie, Alexandria. A deposit of £E10,000 (about 10,260*l*.), or the guarantee of an approved bank, must be sent separately to the Service de la Comptabilité-Générale, Alexandria.

Austria-Hungary: The *Licferungs Anzeiger*, Vienna, states that, of the sixty-one water-works projects for Innsbruck, necessitating a total expenditure of 6,380,000 kronen (about 266,000*l*.), thirty-eight of the most urgent have been passed by the Water-Works Committee of the Imperial Diet, and will be presented by this Committee to the Diet for official sanction. The carrying out of these projects will necessitate an expenditure of 3,345,000 kronen (about 139,000*l*.), and several years will be occupied in completing the works.

Italy: The *Gazzetta Ufficiale*, Rome, contains a notice inviting tenders on behalf of the Commune di Marano Marchesato for the construction of a conduit for the supply of drinking water. Tenders will be received, up to July 20, at the Casa Comunale of Marano Marchesato. The upset price for the cost of material and construction is put at 82,788 lire (about 3310*l*.). The *Gazzetta* also notifies that tenders will be received up to July 28, at the Ministero dei Lavori Pubblici, for the construction of an addition to the mole, as well as the construction of a wharf and a slipway for ships in the port of Riposto. The total upset price of the work is put at 1,118,300 lire (about 44,730*l*.). The *Gazzetta* further publishes a notice to the effect that tenders are invited by the Ufficio delle fortificazioni di Venezia Campo S. Angelo No. 3549 for the construction of a wet dock for the Direzione d'Artiglieria, in the island of S. Giorgio Maggiore, Venice. Tenders will be received at the above-mentioned address up to July 16. The upset price of the work is put at 246,000 lire (about 9840*l*.). Although the foregoing contracts will doubtless be awarded to Italian firms, nevertheless the carrying out of the works may involve the purchase of materials and accessories outside Italy.

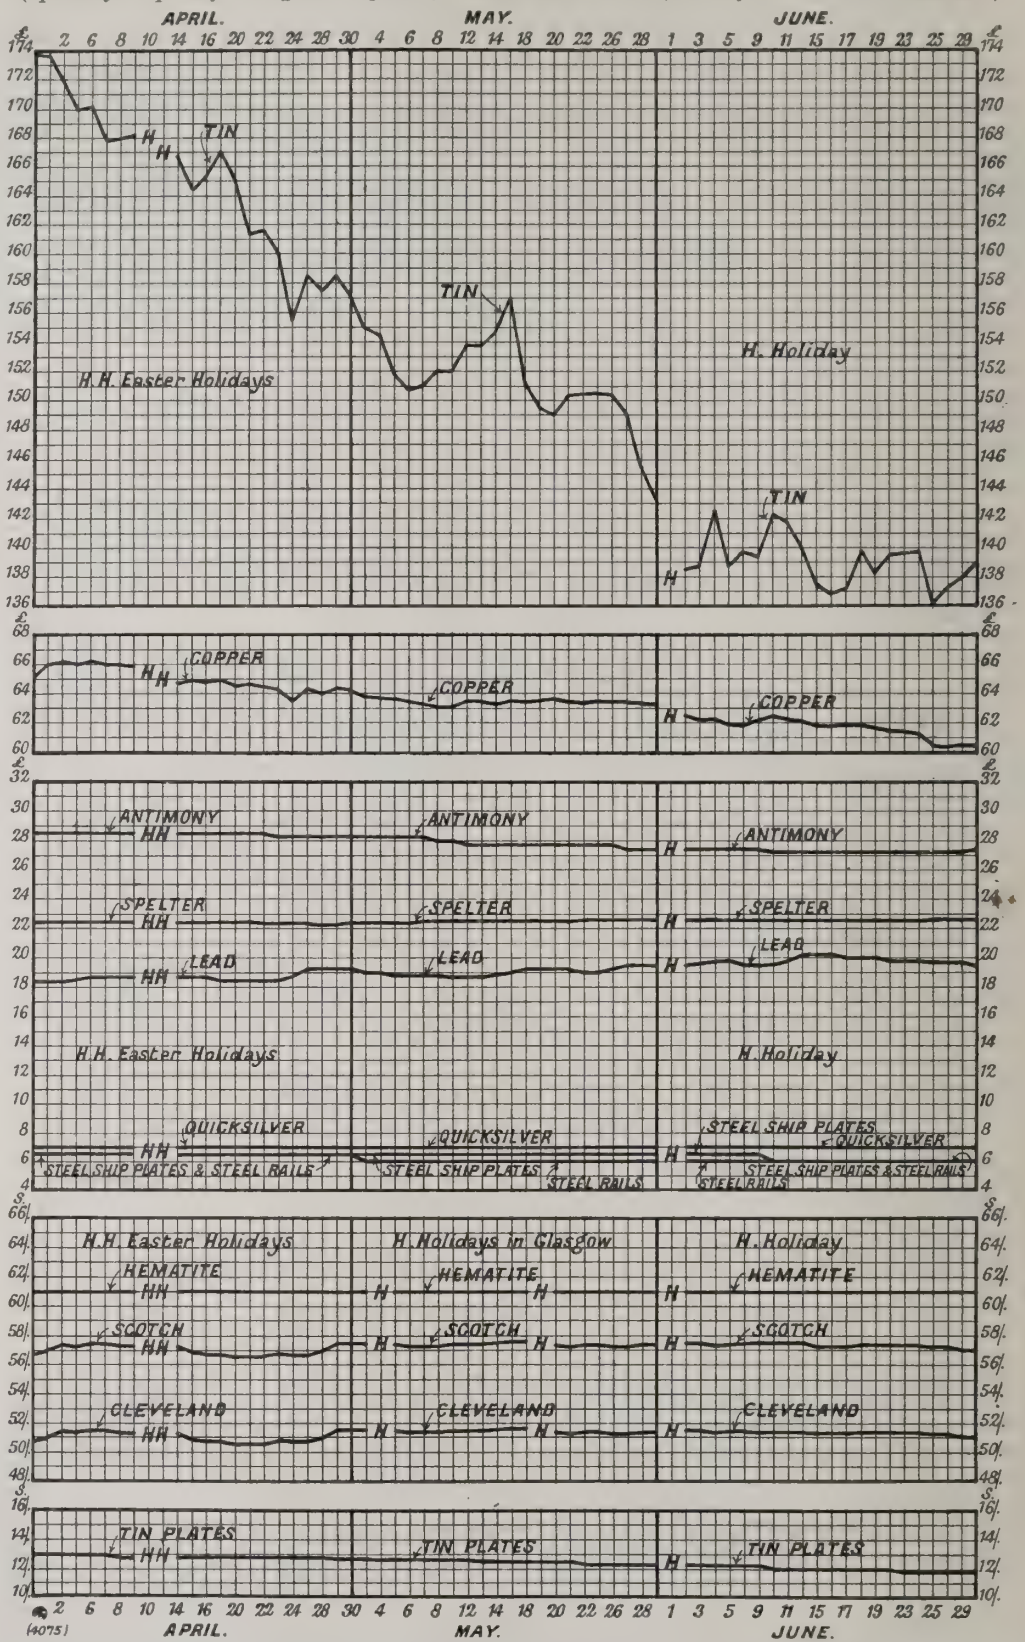
AMERICAN COAL FOR ITALY.—In the course of May three steamers brought 18,000 tons of American coal to Leghorn from Norfolk, Virginia. The coal was intended to be used upon the Italian State Railways, and it is the first brought to Leghorn from the United States for that purpose.

GERMAN RAILWAYS.—The German Government has been authorised to devote 25,310,550*l*. to the development and improvement of the German railway system. The Prussian Government has ceded the Wilhelmshaven and Aldensburg line to the Grand Duchy of Aldensburg for 1,150,000*l*.

TRIPLEX SAFETY GLASS.—On Saturday, June 27, some remarkable results were obtained, at Lord Stanhope's private range at Chevening Park, in testing the resisting properties of bi-triplex glass as manufactured by the Triplex Safety Glass Company, Albermarle-street, W. An Army service rifle and ammunition (mark VII.) were used at a range of 300 yards only, with the following results:—1. Bi-triplex, $1\frac{3}{4}$ in. thick. The bullet struck it almost in the centre, but only penetrated the first thin layer of glass $\frac{1}{10}$in. thick; the intermediate and back sheets were cracked; the back, however, remained perfectly smooth. 2. Bi-triplex, $1\frac{3}{8}$ in. thick. The bullet in this case struck the bottom left-hand corner, penetrating one layer of glass and one of xylonite, but without going any further. The back sheet of glass was slightly bulged. 3. Bi-triplex, $1\frac{1}{4}$ in. thick. This piece was somewhat badly damaged, but the bullet, as in the previous cases, did not go through. 4. This last was a piece of ordinary $\frac{1}{4}$-in. thick triplex safety glass (18 in. by 18 in.), such as is used in motor-coach work and wind-screens; the range in this case was 50 yards, with the same ammunition. Six bullets were fired through this piece of glass, making the same number of clean holes about the size of a threepenny-piece, but this even did not seem to make any difference to the strength of the glass as a whole. The wonderful properties of bi-triplex glass will surely make it invaluable for such purposes as look-outs in the conning-towers of submarines, port-holes, deck-house lights, and bridge-screens on destroyers, battle-ships, and no doubt for many other uses in the military, naval, and merchant services. In spite of the fact that this bi-triplex glass is built up of layers of glass and sheets of xylonite, the difference in transparency between it and ordinary plate-glass of the same thickness is so slight that it is difficult to distinguish the one from the other. Another important point is that although this glass may be very badly cracked, it still remains air-tight and water-proof on account of the sheets of xylonite, which do not crack, being between the layers of glass.

DIAGRAMS OF THREE MONTHS' FLUCTUATIONS IN PRICES OF METALS.

(Specially compiled from Official Reports of London Metal and Scotch Pig-Iron Warrant Markets.)



IN the accompanying diagrams each vertical line represents a market day, and each horizontal line represents 1s. in the case of tin-plates, hematite, Scotch and Cleveland iron, and 1*l*. in all other cases. The price of quicksilver is per bottle, the contents of which vary in weight from 70 lb. to 80 lb. The metal prices are per ton. Heavy steel rails are to Middlesbrough quotations. Tin-plates are per box of I.C. cokes.

COMPLIMENTARY DINNER TO SIR JOHN SNELL.—A general desire having been expressed that the honour of knighthood recently conferred upon Sir John F. C. Snell, President-Elect of the Institution of Electrical Engineers, should be made the occasion of a complimentary dinner in the early autumn, a committee is in course of formation to make the necessary arrangements. Those wishing to associate themselves with the event—and there are certain to be many—are requested to send their names as soon as possible to any of the following:—P. F. Rowell, The Institution of Electrical Engineers, Victoria Embankment, W.C.; D. N. Dunlop, British Electrical and Allied Manufacturers' Association, King's House, Kingsway, W.C.; A. H. Dykes, Association of Consulting Engineers, 11, Victoria-street, S.W.; H. F. Proctor, Incorporated Municipal Electrical Association, The Exchange, Corn-street, Bristol; L. G. Tate, Electrical Contractors' Association, 20, Bucklersbury, E.C.

THE COOLIDGE LAMP.—It is announced at the Massachusetts Institute of Technology that the Rumford medal of the American Academy of Arts and Sciences has been awarded to William David Coolidge, assistant-director of the Research Laboratory of the General Electric Company at Schenectady. The award was made for his invention of ductile tungsten and its application in the production of radiation. The world will recognise in Dr. Coolidge the producer of the tungsten lamp, and near the end of last year the new X-ray lamp, which has greater penetrative power than the older, familiar form. The tungsten lamp produces light with so much less consumption of power that a well-known authority on the subject, speaking three years ago, said that the economic value of it was such that the electric lighting of the day was costing 240,000,000 dols. a year less than if it were done with the old four-watt carbon filament lamps of only ten years before.

THE INSTITUTION OF MECHANICAL ENGINEERS.

(*Concluded from page* 43.)

ON members reassembling in the hall of the Société des Ingenieurs Civils, last Wednesday morning, the chair was again occupied by Mr. Michael Longridge, Vice-President, and the first paper to be taken was one by Mr. Jules Niclausse, of Paris.

THE NICLAUSSE HIGH-DUTY MARINE BOILER.

This paper was entitled "The New Niclausse High-Duty Marine-Type Boiler." In the unavoidable absence of the author, Mr. A. Niclausse said a few words of introduction, after which the paper was abstracted by Mr. W. Y. Lewis. The paper is reproduced on another page of the present issue of ENGINEERING, and it is therefore unnecessary to summarise it here.

After a vote of thanks had been proposed by the Chairman, Mr. Michael Longridge, and passed, Mr. W. Hanning said he would like to make a few remarks on Messrs. Niclausse. Their boiler was widely used in France, and in the French Navy. It was greatly favoured, and the firm had therefore a wide experience, such as should recommend it for adoption in England. Mr. Niclausse had long been associated with British engineers, and was a great admirer of British practice, and he thought every support should be given to his efforts in the direction of progress.

Professor D. A. Low had a suggestion to make with regard to the figures at the close of the paper. He thought the performance should be given per square foot of grate area and per square foot of heating surface, so that reference to other tests would be facilitated.

The next speaker was Mr. W. H. Patchell, who said he had always been interested in the Niclausse boiler, and he was sorry that it had not secured a better showing in England many years ago. They were now being driven to water-tube boilers on account of questions of ground space. Niclausse was the first to use short tubes. The advantage of the first third of a tube compared with the last two-thirds had been amply demonstrated. He thought some additions might be made to the paper. The claim for such high efficiency, he thought, was probably correct, but there was nothing whatever in the paper by which to check it. An efficiency of 91.5 per cent. was pretty high, and he would like to know what happened to the other 8.5 per cent. How much of it went up the chimney, how much was lost in the ashes and in radiation? He thought there was hardly enough to divide satisfactorily between these losses. The boiler was one without a superheater. In that case it was possible that priming occurred, which would apparently improve the performance. The superheater was now almost regarded as an integral part of the water-tube boiler. He had tried to compare other figures with the 91.5 per cent. given in the paper, but he had nothing at all of the same order. The best figure he could lay his hand on was 74 per cent. for a test of a boiler and economiser combined. With a boiler, economiser, and superheater plant he had a figure of 86.7 per cent. for a semi-tubular boiler, and 86.43 and 87.9 per cent. for two Babcock boilers. Those were lower than the Niclausse boiler, although they included a superheater. An important feature of the Niclausse boiler was, he thought, the feed arrangement. Mr. Niclausse put the bottom rows of tubes in series with the upper rows. It was possible to obtain a better efficiency if a boiler were fed with hot water than with cold. If fed with cold, the natural circulation was often upset, but with hot that was not upset, and all the boiler was called upon to do was to evaporate. The Niclausse system gave a true counter-current circulation. The Bonecourt boiler claimed an efficiency of 95 per cent., but that boiler worked on gas, and if the 95 were multiplied by the efficiency of the gas-producer, the net figure was not nearly so high. It was well known that different efficiencies resulted from different conditions of working, and the paper would be improved if figures were given, so that the efficiencies stated could be checked.

Professor Ed. Sauvage, who was called upon by the Chairman, said he had no remarks to offer, except that the paper showed what could be done by careful and scientific treatment of the design and details, and the use in manufacture of the greatest accuracy obtainable with the very best machinery. It was difficult to get an absolutely precise figure for efficiency; but the rate of combustion was low, and the figure, he thought, about as high as it was possible to obtain.

Mr. Charles Hawksley said he thought the cost of the boiler ought to be stated, and also its duration or life, both of which were necessary to an estimate of its ultimate efficiency.

The Chairman, Mr. M. Longridge, said that the principal guide in adopting any type of boiler was the service for which it was intended. A type suited to the work to be performed should be chosen. The great points about water-tube boilers were economy of space and rapid evaporation. High-speed machines always required more attention than low. The high-speed boiler placed in the hands of a man used only to low-speed plant would inevitably give trouble, with the result that it would be condemned, as happened in England many years ago. He thought the improvements in recent designs of the Niclausse boiler to be the greater inclination and the shortening of the tubes. What was wanted for properly gauging performance was not coal per square foot of grate, but coal per square foot of heating surface, and a figure for heat transmission. He roughly figured it out that the test at the lowest rate of combustion mentioned in the paper gave ½ lb. of coal per square foot of heating surface, while in the high-rate test it was 1⅕ lb. The efficiency in the first case was remarkable, especially in view of the fact that radiation losses were often very large, and might in such cases amount to 15 per cent.; at any rate, 15 per cent. usually disappeared unaccounted for. He would like to know if any special arrangements were made with regard to the grate. How far was this below the tubes? Often grates were placed too close, and bad combustion resulted. As to cost, doubtless Mr. Niclausse would say something; but the durability of a boiler depended upon the character of the work and the class of attention, and could not be definitely stated.

Mr. W. Y. Lewis said that, as far as possible, all the information asked for would be given, as Messrs. Niclausse were quite prepared to disclose full details of the tests, &c. With regard to the evaporation per square foot of heating surface, he could not at the moment give that for the boiler alone, but could do so for the boiler and economiser. Working in one test from feed at 77 deg. Fahr., and producing steam at 256 lb. per sq. in. pressure, it worked out at 5.25 lb. In the high-duty test, burning 46 lb. of coal per hour per sq. ft. of grate area, the evaporation was 10.8 lb. per sq. ft. of heating surface, with feed at 77 deg. Fahr., and producing steam at 256 lb. pressure. These high rates were due to having the inner tube for feeding in one and the same direction. Mr. Niclausse had been able to make more use of the heating surface than was possible with other arrangements. The excellent figures were due to the unique features, which alone made it possible. He was in a position to give the balance figures asked for by Mr. Patchell. When he first saw the balance he thought the figures very high, but had submitted them to certain English engineers, and later some tests had been conducted, which, though of short duration, were accurately carried out with a flying start, and corroborated the result of the French Admiralty. The French Admiralty efficiency figures were based on the low calorific value of the fuel. In England the difference between the high and low values was not sufficiently appreciated. The high was the gross value, while the low was a value corrected for the heat which could not be taken up by the boiler owing to interaction of the hydrogen and oxygen. In the French Admiralty test the heat available per lb. of fuel was 14,000 B.Th.U. The heat transferred to the water was 12,800 B.Th.U., giving an efficiency of 91.5 per cent. The heat lost in products of combustion was 645 B.Th.U., or 4.6 per cent.; in excess air, 180 B.Th.U., or 1.3 per cent.; in evaporation and superheating moisture in the fuel, 17.4 B.Th.U., or 0.1 per cent. The balance, going in radiation, &c., was 356 B.Th.U., or 2.54 per cent. The boiler was compact, and there was not much radiation. Care was taken to insulate it effectively; the figure of 2.54 per cent. was not out of the way, and compared favourably with others of larger size and displacement. Another factor contributing to the high efficiency figure was the fact that the firing was done by hand and by first-class experts. The CO_2 records were excellent. There was a boy or man to open or close the door when any shovelling had to be done. This kept the excess air down. Mr. Patchell referred to the probability that some of the steam might be in the form of water, but the French navy experts were not to be easily taken in on such a point. They had tested the quality of the steam by the salt method, and at the normal rate of working the dryness was almost absolute, while at the high rate the dryness fraction was only 0.9 per cent., which was good. Corrections had been made for that amount. The boiler was fitted with separators, so that even when working at 105 per cent. above the normal rate the wetness was practically, say, 1 per cent. The feed-distributing features of the boiler were good. Testing with different feed temperatures usually affected results, because the circulation of the water was affected. In the boiler described the circulation was positive and always in the same direction, and the results did not differ greatly whether feeding with hot or cold water.

MARINE DIESEL ENGINES.

The next paper to be taken was one by Mr. M. Drosne, and was entitled "Development of Internal-Combustion Engines for Marine Purposes." This paper, which we give on page 99 of the present issue, was summarised by the author, after which Dr. H. S. Hele-Shaw reminded the meeting that two years ago the Institution had had a paper on the Diesel engine by Dr. Diesel himself. All engineers regretted the sad end of that distinguished man. He did not remember Messrs. Schneider's work being referred to in Dr. Diesel's paper. It had been important, however, for they had produced about thirty engines; while two years ago Messrs. Burmeister and Wain had only three, but now had about ten, averaging 1000 to 2000 horse-power. Engines of this type were now doing successfully at sea the work hitherto done by the steam-engine. He was present at a recent trial, at which he was much struck by the ease of manœuvring. Only on one occasion did he see anything like a misfire shown by a puff of smoke out of the funnel. Great difficulties had been encountered with the Diesel engine, and they had been overcome in a remarkable manner. By means of a lantern-slide, which was a cross-section of the Selandia, Dr. Hele-Shaw showed how designers had practically arrived at once at a permanent type of disposition or general arrangement for these engines on board ship. The great question of interest was the rivalry between the two and four-cycle systems. The Selandia and Messrs. Burmeister and Wain's engines were all four cycle. The point of great importance with two-cycle engines was increase of size. On the two-cycle system smaller cylinders were required for the same power. Of Messrs. Schneider's engines some twenty were two-cycle engines, and they were running up to large powers. The motor engineer was just now interested in the application of the two-cycle engine to the motor-bicycle, because it would tend to give equal power for less weight. He had great admiration for Messrs. Schneider, who had put down at great expense the two engines spoken of in the paper, with a view to mastering the requirements of the system, so as to be able subsequently to spring right into successful manufacturing. He thought some standardisation was needed with regard to terms. The internal-combustion engine, the term adopted in the paper, covered gas, oil, and petrol-engines. Dr. Diesel's paper was on the Diesel engines; this one was on the same subject, but the titles did not give that idea.

Mr. A. W. Green said that Dr. Hele-Shaw had forestalled him in remarks he had intended making with regard to the two and four-cycle engines. All the later Schneider engines were on the two cycle system, except one large one for land work, which was four cycle. It would seem that at first sight the two-cycle engine ought to be not only more compact, but also more economical. In that system the cylinder was always doing the work for which it was primarily designed, and the pumping was done in a separate and smaller pump, but the pressure against which the latter worked was higher. It would be interesting if figures could be given for the mechanical efficiency of two and four-cycle engines. He noticed that one engine (*d* in the paper) gave about 300 horse power per cylinder. He took it that the cylinder would be about 20 in. in diameter, which was about the limiting size. That size would require from 2¼ in. to 2½ in. thickness, and up to that it was possible

to work without trouble. He noticed that Messrs. Schneider used cast-steel cylinder-covers; other makers had tried that and abandoned it, reverting to cast iron. On the older engines, two-stage compression had been tried, but now three stage was used. The compressor had to be larger than was wanted for the injection air, in order to recharge the starting apparatus. In Fig. 11 a neat design was shown, but the replacement of a piston-ring would involve a lot of work. Was there any special way of accomplishing that? The scavenging-piston was shown without rings. Was that the case? The system of oil-cooling instead of water-cooling had advantages, since leakage from the cooling system became immaterial. Water leakage, of course, ruined the surfaces of the metal. He would like to know whether it would not be possible to use the forced-lubricating-oil system also for cooling. Why should it not be taken from the bearings up to the piston? It seemed to him that if that could be done, it would simplify matters. It would involve enlarging the passages, of course.

Mr. P. M. Baker said that however good the workmanship of the engine might be, this class of engine was up against a difficult proposition as regards fuel supply. In India, coal of 9000 to 10,000 B.Th.U. per 1 lb. cost from 21s. upwards. The Diesel engine did not pay there for itself unless oil could be purchased for 40s. He would be glad to know if any difficulty threatened in this respect, whether the cost of running made the game worth the candle, and at what sort of prices the Diesel engine would compete with the steam-driven ship.

Mr. H. C. Sparks said that with forced-lubricated steam-engines there used to be great trouble with the bearings getting dry, and some kind of priming arrangement had to be adopted for starting. With Diesel engines the pressures were greater, and he would like to know whether any similar arrangement had proved necessary. The oil consumption was given for fuel only. The lubricating oil was an important matter. Although the circuit was practically a closed one, there were certain losses. What was the amount of the make-up oil needed? He was aware that it was possible to get good guarantees, but there was no doubt that a certain amount of oil vapour did escape during work.

Mr. W. H. Patchell asked if there had been any cases of blood poisoning or illness by oil on ships. There had been such cases on land, where the cubic space was not nearly so restricted as it was at sea.

After a few words by Mr. Hanning on the excellent methods of the Schneider Works, Mr. Drosne replied, saying that the cylinder-covers of the Schneider internal-combustion engines were steel castings, which they had found much more reliable than cast iron, but it was necessary to use crucible cast steel for making the castings, so as not to have fractures, or fissures, which were frequently more dangerous than actual fractures, owing to the risk of water leakage inside the cylinder through such fissures. The price of such castings was high, as much as 1.75 francs per kilogramme. The exhaust-pipe was of drawn steel, surrounded by a welded-steel pipe, forming a water-jacket. The cylinders, casings and frames were also steel castings made with crucible steel. The crank-shaft was of nickel-chromium steel; the connecting-rods and the upper portion of the pistons were of nickel steel. In reply to Mr. Green, the air-compressor was a three-stage machine, so as to obtain for the whole engine satisfactory balancing. There were three cranks at 120 deg. for driving the air-compressor and scavenging-pump; otherwise a two-stage machine could very well be resorted to. The consumption of air for fuel injection was $2\frac{1}{2}$ times the fuel consumption. The air-compressor supplied a little more than was required; a small fraction was thus available to meet any leakage that might occur. The air-compressor could easily be dismounted by lateral doors which were not shown in the illustrations; these doors made it possible to inspect the pistons, piston-rings, and valves.

The oil for cooling followed a different circuit from that followed by the lubricating oil, and each had its own cooler: but the same oil was used for cooling and for lubrication, and this oil had a very high calorific capacity—$1\frac{1}{2}$ times that of ordinary oil. At 140 deg. Cent. it had a viscosity equal to that of water. It had a very high flash-point, and therefore a high degree of safety from the point of view of spontaneous ignition.

The oil consumptions per hour recorded in the case of a two-stroke-cycle engine were as follow:—

For a 1100-horse-power engine, two-stroke cycle, oil fuel: full load, 210 grammes; half load, 230 grammes; quarter load, 255 grammes, per effective horse-power; lubricating oil, 10 to 12 grammes per effective horse-power.

The consumptions in the case of the four-stroke-cycle type were for a 360-effective-horse-power engine:—

Oil fuel: full load, 195 grammes per effective horse-power; lubricating oil, 8 grammes per effective horse-power.

Messrs. Schneider used indifferently Texas or Baku oil. In the case of their cargo-boat France, which we described in a former issue (see ENGINEERING, vol. xcvi., page 491), the fuel consumption was much smaller than that of a steamer which could be compared with the France and which burnt Welsh coal.

BALANCING OF INTERNAL-COMBUSTION ENGINES.

The next paper was one by Mr. H. F. Fullagar, entitled "Balancing of Internal-Combustion Engines." In the absence of the author it was given in abstract form by Mr. W. Hanning. This paper we also print *in extenso* elsewhere in our present issue. It was followed by a very brief discussion.

Sir R. Paget said that people generally, and even engineers, had an idea that balancing might be beneficial, but few understood that it was of the fundamental importance it really was. Perfect balance involved the balance of all forces. In the Fullagar engine a force acted on two pistons, and the thrust was thus divided and balanced. The stresses were reduced. There was no fear of the cylinder-cover blowing off. The force necessary for compression was applied by a direct system of tie-rods. The force of the explosion was divided into two; the crank-shaft received nothing but direct, equal and opposite impulses, and could be made lighter. The engine weighed half the amount per horse-power of that of the ordinary engine. If the principle were applied to the Diesel engine, the weight could be halved.

IMPROVEMENTS IN MOTOR-LORRIES.

As time was rapidly advancing, the discussion on Mr. Fullagar's paper was closured, and a paper, which we shall publish in a future issue, by M. Brillié on "Improvements in Motor-Lorries; Self-Loading; also Driving and Steering Through all Four Wheels," was taken as read, the discussion on it being opened by Mr. L. A. Legros.

Mr. A. L. Legros said the paper dealt with two different types of vehicles. He believed that for the first one the number of platforms necessary was not stated; he thought that more than one platform would be required. The second vehicle was much more interesting than the first, but it was not entirely new, since one of a similar type was shown in 1904 at the Crystal Palace, built by Spyker. Mr. Legros then showed on the blackboard how trouble could occur by steering by both the back and front wheels, the vehicle being unable to leave a kerb unless there was ample room to allow of steering. It was necessary that there should be a differential on both axles and on the connecting-shaft.

Mr. Henry Fowler followed, speaking first on the movable platform described by the author. He thought that platform would add considerably to the weight, a question which they always had to keep in view in England. That would tell against its use there. Then the wheels were so small that he did not think it would be suitable for any but very level floors. He had had some experience lately with small electric lorries, of which the ease of manipulation was extraordinary. In one case a very unskilled man had in less than a week a wonderful control of the machine, and ran it in and out in shops among large machines without the least difficulty. In the large vehicle, however, these additional features increased the cost, weight, and complication, and then it was a question whether there was going to be any real advantage.

Dr. H. S. Hele-Shaw said he had had some experience with driving and steering on all four wheels, and the difficulty of getting away from the kerb mentioned by Mr. Legros was a real one. Nevertheless, the manœuvring capabilities of such machines were marvellous. They had found that it was impossible to drive two axles from a single drive. It had been tried, but the efficiency was about nil. Direct coupling was impossible for road work. Owing to the irregularity of the ground, the axles pulled against each other. If they were uncoupled and driven separately, the efficiency went up. He would like to know whether the machine described had a continuous drive right through to both axles.

As the time for adjournment had passed, the discussion was closed, and the usual votes of thanks were accorded to all who had contributed to the pleasure or the success of the visit, or would do so before its close. These votes included, of course, especial thanks to the Société des Ingénieurs Civils, Mr. and Mrs. H. Gall, Mr. and Mrs. W. Hanning, the various works, clubs, &c., and also to Mr. Eiffel, and to Mr. Sartiaux and the Chemin de fer du Nord and other railways.

In our account of the earlier proceedings, in our issue of last week, we made mention of the various events which took place on the Tuesday, Wednesday, and Thursday. It only remains for us to mention that the excursions arranged for the Friday were eminently successful. Members were divided in their interests, but the largest party left Paris on Thursday evening for Lille, where on the Friday morning parties were made up for different works. One party visited the general engineering works of the Compagnie de Fives-Lille, where they were cordially received by MM. Salmon and Richards. The works in question employ about 4000 hands, and have an area of 62 acres, of which $22\frac{1}{2}$ are under cover. The variety of the work in hand created a great deal of interest. It ranged from bridge-work and roofing to locomotives, turbines, gun-turrets, cane-crushing plant, &c. The finest shop was in the structural steelwork department, where one building has a length of 1308 ft. and a width of 148 ft. For a considerable portion of the length of this shop the floor is unobstructed by pillars, although it is virtually of two bays. Strong cross-girders span the shop and carry the roofing, carrying also lengthwise down the centre of the shop an overhead girder supporting rails for overhead cranes. One of the cranes is provided with a revolving jib, so as to enable it to deliver to, or pick up work from under, the neighbouring crane. At the conclusion of the visit the party returned to the Hôtel de la Paix, where it was joined at luncheon by MM. Salmon and Richards. After lunch several speeches were made thanking these gentlemen, the Compagnie Française Thomson-Houston, Mr. W. Hanning, and Mr. Walker, of Lille, for the courtesies extended by them to members of the Institution. Mention should also be made of the particularly genial co-operation of Mr. Sire, of the Northern Railway, a company who did everything possible in the way of providing railway facilities to add to the enjoyment of the trip. An additional excursion was arranged at the invitation of the Northern Railway for Saturday, and many members availed themselves of thus terminating the visit with an enjoyable day's sightseeing.

THE NATIONAL PHYSICAL LABORATORY IN 1913-14.

(*Concluded from page* 31.)

Heat (Messrs. J. A. Harker, D.Sc., F.R.S., G. W. C. Kaye, D Sc., W. Hugo, A. Blackie, B.A., W. F. H. Higgins, B.Sc., and B. Wilson, B.A.). *International Temperature Scale.*—This question, raised by the President of the Reichsanstalt in 1911, has been submitted to a sub-committee, consisting of Lord Rayleigh, Professor Callendar, and Dr. Harker, and recommendations are soon to be published by the national institutions at Berlin and Teddington, and also by those of Paris and Washington.

Emissivity of Matter at High Temperatures.—The phenomena of electric and thermal emissivity of matter, and of sublimation and cathodic sputtering, which are correlated, have further been investigated by Messrs. Kaye, Higgins, and Dr. Donald Ewen. We dwelt at some length upon these researches last year,* and in connection with Dr. Harker's Royal Institution lectures.† One of the new furnace arrangements is illustrated in Fig. 9. The carbon furnace tube has a length of 75 cm., a thickness of 4 mm., and an internal diameter of 30 mm.; the central portion only is heated up to 2000 deg.

* See ENGINEERING, July 4, 1913, page 3.
† *Ibid.*, March 27, 1914, page 290.

or 2500 deg. Cent.; as some of the fumes attacked the carbon, the furnace-tube proper was lined with a thin carbon tube, which was renewed occasionally. The graphite crucible has an internal diameter of 5.5 mm. Since almost every substance, carbon included, seems to give off charged (and also other) particles, electrons or ions, at high temperatures, a differential test was applied, the ionisations being first determined with the crucible empty and then with the crucible charged with material. The ionisation currents were measured both between the crucible and furnace-wall and between that wall and a special hollow carbon electrode, kept cool by water streaming through a brass tube within the carbon. The introduction of the powdered material into the hot zone of the furnace gave rise to a violent ebullition, and the smoke or flame issuing from the open furnace-mouth frequently showed a colour complementary

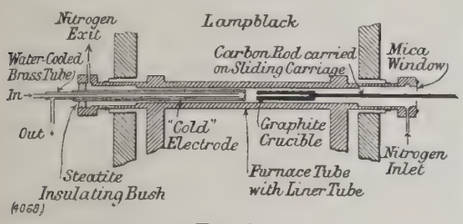


FIG. 9.

to the colour generally ascribed to the vapours; thus calcium oxide gave a yellow-green cloud (not reddish), barium oxide a salmon-pink (not green), strontia (characterised by a beautiful crimson colour) a beautiful green, aluminium a brilliant yellow, its oxide a green, &c. In addition to the substances stated, iron oxide, silica (silver sand), and the metals tin, copper, iron and brass were tried.

The vaporisation of all these substances caused a considerable increase in the ionisation currents. Those currents might be electronic, depending on temperature only, or they might be due to chemical reactions or to change of state, vaporisation or liquefaction; most likely all three causes come into play, and chemical combination plays a chief part. Carbides may be formed, and nitrogen—nitrogen was generally passed through the furnace—may react at high temperatures; solid magnesia seemed to melt into carbon at 1900 deg., as molten iron eats its way through a graphite crucible; oxygen, sometimes admitted, increased the electrode current. All the substances, except tin, emitted negative particles; the ionisation currents were strong, up to 4 amperes per sq. cm. It will be understood that the external electric current only served for heating the tube, no other external potential being applied. Yet that electric heating may have some influence; for Fredenhagen observed in similar experiments* that his ionisation currents produced by direct electric heating of the electrode went down to 1 per cent. of their value when the heating was indirect in a vacuum furnace. The ionisation currents increase as the temperature rises; and if that should continue at the same rate, the ionisation currents would account for Hale's powerful magnetic fields in the neighbourhood of sun-spots.

The experiments on the sublimation of hot metals were partly made with apparatus resembling that illustrated in July last, and partly by placing between the iron strip, directly heated by the current, and a screen, a shield of platinum provided with a central hole and further away with a platinum stop, so that the vaporised particles had to pass through two holes before being deposited on the screen. Like Reboul and de Bollemont, whose researches we have noticed, Dr. Kaye assumes that two kinds of particles are shot off: ordinary particles, probably neutral, shot off at all angles; and electrified particles, shot off at right angles only, and thus giving sharp shadow pictures, but only at a short range of about 1 cm. (for iron) *in vacuo*. The difference between the two kinds of particles may chiefly be one of size, however. At high temperatures the charges are always negative, as we mentioned before. When an aluminium cathode is volatilised in a helium tube, the disintegration of the aluminium proceeds only from the edges, whilst the directly heated strips of iron and platinum become pitted as if etched. In these latter experiments a vacuum is maintained, whilst those previously mentioned took place at ordinary pressure.

* See *Physikalische Zeitschrift*, 1912, page 539.

Thermal Conductivity of Heat-Insulators. Thermometer Glasses.—The apparatus described last year for determining the thermal conductivity of slabs of heat-insulators, 34 in. square (actual measurements being made on the central area of 10 in. square) has been successfully used by Dr. Kaye and Mr. Higgins for testing granulated cork, slag wool, and charcoal, but the results are, so far, confidential. The research on the secular behaviour of thermometer glasses, Jena 16^{III}, Jena 59^{III}, *verre dur*, Kew glass, concerns thermometers especially made eleven years ago, which for nine years had never been raised above room temperature. The temporary depressions of the zero were determined (Kaye and Wilson) corresponding to 30 deg., 50 deg., 75 deg., and 100 deg. Cent., and afterwards at every 50 deg. Cent. up to the temperature of annealing. The rates of change, studied previously by Mr Hugo, are very small. The analysis (by Mr. Withey) proved, however, that the *verre dur* (supposed to be free from lead) contained up to 6 per cent. of lead.

Petroleum.—Mr. Higgins has extended his comparison of the Engler and the Redwood viscosimeters to the Admiralty No. 2 type of the Redwood apparatus for oil fuel, so designed that the time of flow should be only a tenth of that required by the older pattern. The viscosities and densities of oils have also been determined for the temperature range 32 deg. to 120 deg. Fahr.; further the flash-points of mixtures, and the lowest temperature at which an oil will flash when tested in large vessels holding 5 gallons of oil.

Measuring Air Temperatures.—At the request of the Geodetic Survey of India the Laboratory designed an apparatus (made by Mr. R. Paul) for measuring air temperatures within 0.1 deg., at heights up to 150 ft. above the ground, at intervals of 15 ft., a question of importance with respect to the corrections to be made for refraction in geodetic work. As mirror galvanometers were out of question, Mr. Blackie made the following arrangement:—A manganin wire runs up the mast of 150 ft., and down again. On the latter side ten platinum resistance thermometers are inserted in series, and potentiometer leads are taken down from the two ends of each thermometer. Down below is a battery and a swamping resistance, which balances the other resistances at a certain temperature. The thermometer-frames are suspended vertically, and each is shielded above and below by screens of balloon fabric (aluminium coated) against solar radiation from above and terrestrial radiation from below: four of these screens are horizontal, and a fifth, above, is roof-shaped.

Mr. Blackie has also investigated, for the Advisory Committee on Aeronautics, the permeability of balloon fabrics to radiant heat with the aid of an apparatus which allows of the determination of secondary radiation, convection, and of the total emissivities of the fabrics in still air, at temperatures from 3 deg. to 30 deg. Cent. above the surrounding atmosphere.

New Furnaces.—The new equipment comprises a regenerative muffle furnace and a similar salt-bath furnace, in which temperatures of 1300 deg. and of 1000 deg. Cent. can be reached without blast. The former furnace is intended for black-body tests on pyrometers; the latter for the comparison of thermo-couples and resistance thermometers, which are inserted in iron tubes dipping into iron pots, $2\frac{1}{2}$ ft. deep, the salt-bath containing a mixture of sodium and potassium chlorides. In a third similar furnace a temperature of 1400 deg. Cent. can be attained without blast.

The new work projected comprises an investigation of the specific heats and latent heats of fusion of metals by the methods of Harker and Greenwood, a subject on which very little reliable information is available. Expansion coefficients and the properties of refractories are also to be investigated. For the expansion tests Dr. Harker uses tubes—*e.g.*, oxygen-cylinders inserted in baths, at various temperatures—and places in the tube first a rod of the metal in question, resting below on a footstep. On the metal he places a rod of silica which extends through the upper end of the tube, bearing against a micrometer screw; thus only the upper end of the quartz rod is exposed to cooling.

Thermometry.—To meet the transfer of the work from Kew, the Thermometry Department has been reorganised, and the work is now, under the superintendence of Dr. Kaye, carried out in three divisions (for high-precision, medium-precision, and clinical instruments), under Messrs. Hugo, G. Badderley, and A. C. Cooper. The baths, lagged with granulated cork, which we described last year, on page 3 of our issue of July 3, 1913, keep the heat very well. The capacities of the baths are 51,000, 26,500, and 17,500 cub. cm.; to cool them with the heating current off, but the stirrers on, from 90 deg. to 80 deg. Cent., took $1\frac{3}{4}$, —, $\frac{3}{4}$ hour; from 40 deg. to 30 deg. Cent., $11\frac{1}{2}$, $5\frac{3}{4}$, $6\frac{1}{4}$ hours; and from 30 deg. to 20 deg. Cent., 40, 18, 20 hours. Low-temperature testing is done with the aid of a vacuum-jacketed bath of acetone and solid carbon dioxide; oil circulating through a worm immersed in a freezing mixture of ice and salt is used for testing meteorological thermometers.

Radium Room.—The British National Radium Standard has been placed in charge of Dr. Kaye, in the new Radium Room, which has been fitted up with the assistance of Sir Ernest Rutherford. The international standard of radium chloride at Sevres was prepared by Mme. Curie; the British standard of 21.1 milligrammes of radium chloride—costing 354*l.*, the donation of Dr. G. T. Beilby, F.R.S.—was prepared by Stefan Meyer in Vienna, and was compared with her own standard by Mme. Curie. The outfit of the room comprises a 1000-volt battery by Klinkerfuess (formed lead strips in sulphuric acid in test-tubes, terminals with umbrella insulators), a Paschen galvanometer, Dolezalek electrometer, and three apparatus for standardising the radium salt in terms of metallic radium, which is the practice of the Reichsanstalt. The three apparatus are based upon the ionisation due to gamma-ray activity, which attains its maximum in sealed tubes after five or six weeks; the rays then measured have to pass through 5 mm. of lead. The first handy apparatus is simply an ionisation chamber, combined with an electrometer, the radium preparation being mounted on a carrier moving on an optical bench. The second apparatus, method of Rutherford and Chadwick, balances the ionisation produced against that of a deposited film of uranium oxide, after McCoy; the apparatus consists of a kind of photometer bench, an ionisation chamber of lead, and a lead tube (10 ft. long) leading from the chamber to the instrument-box; the tube is made long, so as to keep the radium away from the instrument, and is evacuated; calculations are based on the inverse square law. The third method is modelled on one due to Mme. Curie. An aluminium plate, 60 cm. in diameter, lies between two stout plates of lead, being separated from them by air-gaps of 2 mm. and ebonite blocks; the inner plate is insulated and joined to an electrometer; the two outer plates are charged to a high potential; the sample is laid on the centre of the upper plate, and the strong gamma-ray radiation is measured in the air-gap. More than 3000*l.* worth of radium have already been tested.

Metrology (Messrs. J. E. Sears, M.A., S. W. Attwell, H. L. P. Jolly, B.A., E. A. Owen, M.Sc., E. G. Constable, F. H. Rolt, F. A. Gould, B.A., V. Stott, B.A.).—The department has not only had to transfer the work from Kew, but the demands for Kew work so much exceeded those of previous years that a congestion arose; the increase in watches, chronometers, barometers, and hydrometers was very large, and the accommodation available is insufficient; thus an extension of the metrology building appears urgent. Serious—*i.e.*, long-continued—trouble has, moreover, arisen with respect to the maintenance of the standards; some comparative measurements made at Sèvres and at Teddington would not agree, and the silica metre bar, on which such great hopes had been placed, seemed to behave capriciously. The discrepancies involved were, of course, exceedingly small; but they could not be disregarded. Most of them have now been accounted for, and the reputation of the silica metre has been vindicated; but the report of Mr. Sears shows how much anxiety and labour those recomparisons have caused.

Pure Measurement. Line Measures.—As regards the 4-metre bars for the Laboratory and the India Office the determinations made at Sèvres and at Teddington were in excellent accord; the Laboratory bar had been sent over to Sèvres for verification in connection with the 24-metre wires. The accord of the measurements of the seven 1-metre bars (of nickel, 43 per cent. nickel steel, and invar) was also very satisfactory; but there were

puzzling discrepancies which were finally traced to the 1-metre comparator. The slide carrying the microscopes is rigidly bolted to the main framework, on ways cast solid with which the water-tank runs; any strains set up in the framework by moving the tank (weighing 300 lb. full of water) from one position to another was liable to produce distortion in the slide, and thus to disturb the axes of the microscopes. If this effect had been constant, either positive or negative, for measurements on the back girder or on the front girder of the comparator, it could have been eliminated by interchanging the bars after finishing half the observations This had, indeed, been Mr. Sears' practice. But some irregularity remained, and this has temporarily been cured by making the microscope slide, though still bearing on the framework carrying the tank, rest on a three-point support; but a new comparator is wanted. There were also discrepancies as to the expansion coefficients of the nickel bars of the National Physical Laboratory and of the India Office, the latter of which had been certified at Sèvres; both bars had to be sent over there, and it finally resulted that the India Office bar had changed. The invar bar continues to show a regular growth of 0.9 μ per year, the total measured growth now amounting to 17 μ.

End-Measures. Screw-Gauges.—A new set of end-gauges is badly needed; ordinary gauges are not sufficiently accurate, and the gauges will have to be especially made, and possibly have to be measured several times at the Laboratory during their manufacture before their standardisation. There is an increased demand for the measurement of ring screw-gauges to determine the five elements: full, effective, core diameters, pitch, angle—a task of great difficulty. The core diameter is now measured by means of Johansson gauges. The effective diameter is measured by small hardened-steel balls (from the Hoffman Company), which lie about half-way down the V on the thread, two balls being on one side of the gauge, separated by 3 or 5 threads, and one ball placed opposite; the distance between the balls is measured by the Johansson gauges. The full diameter is measured by a sharp point mounted on a piece having a well-finished base for the attachment of the Johansson gauge, completed with a rounded piece making contact on the crests of the threads opposite the point; the actual dimension measured is $\frac{1}{2}$ (full + core diameter). But special machines should be available for plug and ring screw-gauges, particularly as the Laboratory has to verify the international gauges for pipe-threads. Some Hirth minimeters and Aldis sphere spherometers have been standardised, the latter with the aid of sixteen steel balls ranging from $1\frac{1}{4}$ in. to $2\frac{1}{2}$ in.

Surveying-Tapes and Wires; 50-Metre Base.—The work on tapes and wires involved a research into the reliability of the two 24-metre catenary wires of the Laboratory, as to the standardisation of which Sèvres and Teddington differed. For this purpose the 50-metre invar tape was subdivided every 4 metres and standardised under 10-kg. tension in 4-metre catenaries by direct comparison with the 4-metre bar. The seven lengths of 24 metres (obtained by the addition of any six consecutive 4-metre steps) were then compared with the two 24-metre wires at the front of the 50-metre base. Finally the thermal expansion coefficients of the full lengths of the two wires (which had not been determined at the same temperatures at Sèvres and at Teddington) were redetermined in the 50-metre tank, one wire being placed into it at the time under a tension of 10 kg.; this latter absolute measurement was carried out by Mr. Attwell. It resulted that one of the wires (which, when placed on the floor, coils helically, whilst the other lies straight) is unreliable.

The 50-metre base itself, a curve of whose apparent changes in length we published last year,* has been kept under further observation, and it appears that the comparatively hot summers of 1910, 1911, and 1913 caused temporary increases in the length, whilst there was little increase during the cold summer of 1912. When the probable variations in length in different months and years (due to variations in surface temperature) are subtracted from the observed length, a wavy curve may be drawn through the cluster of points giving monthly means, and this curve has a general upward trend, indicating a very small secular growth of the bench independent of temperature changes, while the waves suggest summer and winter effects (due to general temperature changes in the body of the masonry apart from surface temperature).

Physical Test-Weights. Hydrometers.—It had been observed that the 1000 gramme-mass (copper-nickel, 50 per cent.) seemed to absorb moisture when immersed in water; determinations are therefore now made before and after immersion, and standard weights have been prepared of a special propeller alloy which seems to be free from this soakage difficulty. In determining the mean density of an ellipsoid of platinum-iridium (for dielectric measurements, of a volume of only 0.0958 cm.^{3}) to the fourth decimal, mercury displacement was found unsuitable, and weighing in water was disturbed by surface tension. The difficulty was overcome by suspending two glass carriers, one for the ellipsoid, the other for the weight, by platinum wires from the balance arms into distilled water, exchanging the loads, and by allowing also for the change in surface tension consequent upon the exposure of different lengths of suspending wires. The same difficulty of surface tension crept up in testing Sikes' hydrometers (for excise work) of glass and of metal. The two kinds cannot really be compared in liquids approximating the density of water, because these liquids do not wet metal stems, and metal hydrometers are unreliable for this reason. The trouble can, to a certain extent, be overcome by mixing the liquid with a little solution of sodium carbonate, and adding a little alcohol; but that method is not applicable for hydrometers of different sizes, and not for comparing hydrometers of glass and of metal.

Barometers. Barographs.—The ventilation and temperature control of the inner rooms of the metrology building, in which a constant temperature should be maintained, had been effected by sending a continuous supply of warm air into these rooms by a series of small fans. This arrangement, adopted when the building was erected some years ago, did not answer well when the rooms became crowded, and for the past two years the system has been reversed, cold air being drawn in through the outlet trunks. But fans are altogether out of question in rooms where mercurial barometers are tested, and other arrangements will have to be made in the projected extension. In connection with the international adoption of the "baromil," to which we have referred on other occasions, we should mention that a baromil is defined as the height of a column of mercury, which at 0 deg. Cent. in latitude 45 deg., at sea-level, produces a pressure of one millibar — *i.e.*, 1 kilodyne (10^3 dynes) per sq. cm; the equivalents are: 1 in. = 33.8632 baromils = 25.4 mm. The comparisons are not facilitated by the fact that inch scales are graduated at 62 deg. Fahr., and millimetre and baromil scales at 0 deg. Cent.

The method in which barograph curves obtained on flying-machines are tested is interesting. The instruments are received as used, except that the pointer is lifted from the paper. The clockwork is set going, and the instrument is placed in one of the glass cylinders used for testing aneroids at different air pressures. The pressure is then adjusted so that the pointer falls on the beginning of the curve and afterwards follows the curve, the corresponding standard pressure on a gauge barometer being read at intervals. If then the date, hour and place of ascent, its height above sea-level, and the difference between surface pressure and maximum pressure are known, the height to which the aeroplane rose can be calculated—to ± 200 ft. in the case of two barographs submitted

Chronometers, Watches, Clocks (Mr. Constable).—We have already mentioned that radiotelegraphic time signals are received from Norddeich and the Eiffel Tower; these two signals agree, whilst the telegraphic signal from Greenwich comes about 0.2 second later. The unit in watch-testing is now 0.1 second (against 0.25 second formerly), and the testing is done on lines more approaching the Swiss Observatory practice. The number of "especially good" watches had risen; the best marks were again obtained by a foreign watch, from P. Ditisheim, La Chaux-de-Fonds; of 184 chronometer movements 150 were certified.

Taximeters. Blythwood Machine (Messrs. H. A. Dear and J. K. Enock).—The work had been affected by the strike of 1912, but the number of new taximeters tested in 1913 was greater than in 1912; only one new type has been submitted. Two flexible shafts submitted failed; shafts need not be tested individually, but must be made to approved sample. Mr. Enock is also in charge of the Blythwood grating-ruling machine, which has been provided with new ways for the carriage; the carriage now runs on two cylindrical steel bars, with two V's on the front, and with a flat on the back bar; a finger projects downwards from the carriage on either side of the screw, and the motion is transmitted from the nut to the two fingers by means of a gimbal-ring, so that the carriage moves as though connected to the nut at a point on the axis of the screw; the nut is in two halves, and each half is independently prevented from rotating by an arm which rests on one of the way-bars. The machine rules (up to 14,400 lines to the inch) only on the forward stroke; special gratings, like those for Professor Bragg, which we mentioned recently, are produced by missing one or more strokes. The new gratings now appear free from the erratic errors given by the rolling carriage; but there is still some trouble with large rulings.

The Silica Metre.—It has already been mentioned that the apparent behaviour of the silica metre of the Laboratory suggested the need of a modified annealing. The trouble was, however, traced to the comparator, and applying the corrections to previous measurements, it is found that the fluctuation in length of 0.5 μ probably represents the average. But there is apparently a growth in length of 2 μ annually in the case of the silica metre for the India Office, which has not settled down yet to constant dimensions in the nine months during which it has been under observation.

Miscellaneous.—Rubber templates, it appears, may shrink by more than 1 per cent., chiefly in early life. The researches, undertaken for the Engineering Standards Committee, on British Association screw threads (neither the pitches nor the diameters of the tapped holes agree exactly with those of the taps), on bayonet-socket lamp-holders, and on sparking-plugs are being continued.

Optics (Messrs. T. Smith, B.A., R. W. Cheshire, B.A., and J. Guild).—The transference of the Kew works and the equipment of the new spacious rooms, which we briefly noticed last year, has left little time for research work. The question of improvement of the manufacture of optical glasses has suffered from the death of the chairman of that committee, Sir David Gill; but a report is now under consideration. The equipment has advanced slowly, not only for want of means, but also because the staff are modifying some methods of testing; they are preparing a revised edition of the test pamphlet, and proceed cautiously in innovations, wishing first to thoroughly study the theory of the Kew tests and the instruments used. Although, as we mentioned in our introduction, some of the simple test-work has fallen off, the higher class work for the Admiralty and others has become more heavy, fully justifying the expenditure on the new commodious quarters of the department. The iron bench is a semi-circle, 46 cm. in width, 145 cm. internal radius, resting on 6-in. iron pillars, through which the cooling and heating water circulate; the bench rests on concrete foundations 152 cm. above the floor, a convenient height. When it was completed the Kew collimators were mounted on it and bolted to the plane upper surface of the bench. The altitude circle for theodolite-testing is not yet completed; so far only the vertical iron horse-shoe can be seen. Scales of degrees have been fixed on the roof on the tank building (extending over 11 deg.) to the west, and in the meadow to the east of the building (extending over 20 deg.); all the posts are bedded in concrete, and the black lines denoting degrees and quarter-degrees are formed of boards nailed to the background boards, which are painted white. The test objects brought from Kew have been refixed, and at distances of 100 ft., 200 ft., 300 ft., 400 ft., and 500 ft. from the vertical scale phosphor-bronze rods have been embedded in the cement below the turf-level.

Ships' Lights.—In connection with the work of the Photometric Department on ships' lights for the Admiralty, lenses have been designed to fit the Navy lantern and to give the distribution of light from an oil-lamp desired by the Admiralty—viz., symmetrical illumination about a vertical axis through an azimuth angle of 135 deg., and in a vertical plane an illumination represented by the unit 1 from 5 deg. above to 5 deg. below the horizontal, diminishing uniformly both above and below the horizontal from illumination 1 at 5 deg.

* See ENGINEERING, June 27, 1913, page 860.

to illumination $\frac{1}{4}$ at 20 deg. Lenses made to this design have given satisfactory results.

The report describes the new optics building at some length. We noticed some of the chief features last year, when the buildings were opened, the general arrangements, the cream-tiled "dark" rooms, the double light-trap doors, with their peculiarly-recessed posts and doors, effectively to shut out all light, &c. An appendix to the report contains historical notes on optical tests at Kew Observatory, which, it appears, began in 1860, when sextants were tested with apparatus which Francis Galton bought at his own expense.

Tide Prediction (Messrs. F. J. Selby, M.A., and W. H. H. Brookes).—The department advised on modifications in a machine which Messrs. Kelvin, Bottomley and Baird constructed for the Japanese Hydrographic Office. Work on the Indian tide-tables for 1916 is advanced.

The Library (Messrs. Selby and Hodgson).—Mr. Selby, who acts as secretary to the National Physical Laboratory, is also librarian of the new White library, which should receive general liberal support; back volumes of the leading journals would particularly be welcomed.

THE JOINT MEETING OF NAVAL ARCHITECTS AND ENGINEERS AT NEWCASTLE.

(*Concluded from page* 63.)

TWO-CYCLE GAS-ENGINES.

AT the meeting held in the Institution of Mining at 10 A.M. on the morning of the 8th inst, Mr. Summers Hunter was in the chair. The first paper taken was by Professor B. Hopkinson, and was entitled "The Charging of Two-Cycle Internal-Combustion Engines." It was summarised by the author. We reprint the paper on page 100. The second paper was by Mr. H. F. Fullagar, and was entitled "A New Type of Internal-Combustion Engine." It was read by its author. We do not reprint the paper, but a description of the leading feature of the engine will be found in a paper read by Mr. Fullagar before the Institution of Mechanical Engineers at Paris, which is reprinted on page 103.

Professor R. L. Weighton was the first speaker in the discussion, which was taken jointly on the two papers. He said that having had little time to study either communication, any remarks he made would be of only a general nature. The first paper dealt with a subject that was at the root of the efficiency of internal-combustion engines. Professor Hopkinson had naturally had to make certain assumptions, and quite possibly the coefficients he suggested would have to be modified in the light of future experience. He did not think, however, that anyone could have carried the matter further mathematically than Professor Hopkinson had done, and he saw no reason to suppose that, when final coefficients were evolved, the method should not form the basis of a directly practical method of designing internal-combustion engines.

Turning to the Fullagar engine, he would say he saw it for the first time the day before, and anything he said must be taken as a result of first impressions. He must confess, however, that those impressions were very favourable. He thought the use of open-ended cylinders with double pistons was ideal. Mr. Fullagar seemed to have improved on the best type of Junkers engine. Junkers obtained a beautiful mechanism, by which what he might term the useless forces—the forces used in compression—were not transmitted to the crank-shaft. He required three cranks, however, and tandem pistons, leading to a very high engine. Mr. Fullagar seemed to obtain all the same advantages, without the disadvantages, merely by the use of his oblique rods. The only objection he could see which anyone might raise against the engine would be on the score of these rods; but he did not think they would necessarily weigh against the advantages.

The balancing of the engine was very perfect, and, from a practical point of view, it seemed to have all the elements of durability. It had no valves, except, of course, the fuel-valves, the cylinder construction doing away with either exhaust or admission-valves. This was a great simplification. There was a point in this connection, however, which he should mention. Anybody could devise a simple mechanism by which valves were eliminated by causing the piston to cover and uncover ports. It could be done for any sort of engine. He had done it himself for steam-engines, and was, perhaps, sorry afterwards. The arrangement worked all right, but was uneconomical. It was possible by analogy from steam-engines that there would be less economy in a valveless internal-combustion engine than in one having cam-worked valves of the usual type. Against this, however, Professor Hopkinson had found the Fullagar engine economical. It was quite possible the device would be economical, and would show the maximum degree of durability. If he might give some advice, he would suggest that Mr. Fullagar should run his engine continuously and as hard as possible, and should consider the construction of a Diesel on the same principle.

Mr. R. Allen was the next speaker. [We should state that the 500-horse-power Fullagar engine now running at the Gateshead station of the Newcastle Electric Supply Company was built by Messrs. W. H. Allen, Son and Co., Limited, of Bedford.] Mr. Allen said he would like to say something of the work he had been privileged to carry out with Mr. Fullagar during the last three years. Everyone engaged on experimental work knew how frequently it led to nothing but the scrap-heap. In this case, however, the inventor's confidence in his ideas had been justified. Mr. Fullagar had faith enough to build a fairly big engine right away, and his faith had been justified by success. Professor Weighton had spoken of the oblique rods in the engine. It was probable that anyone who saw the engine for the first time would raise this point. Everything else in it was absolutely simple, but this was at least a novelty. He must confess that much of the attention he had given to the engine had been directed to this point. He had been afraid of vibration at first, but Mr. Fullagar had convinced him that there would be no trouble, and finally the engine was built practically to Mr. Fullagar's original drawing. To prevent possible accident when the engine was first run, vertical guides were made for the oblique rods, which had a damping effect. The vibration was very small, however, and there was no trouble whatever. The engine had run perfectly successfully from the first time it was run on their test-bed, and had run for eighteen months since. Much care was taken with the balancing during construction, and each component of the reciprocating parts was weighed separately. The parts of each unit were then weighed together. He thought the success of the engine due to the few working parts, the remarkably low stresses, the small floor space, and the great saving in weight.

Mr. Stokes, the next speaker, wished in the first instance to deal with Professor Hopkinson's paper. He did not think the inferior output of two-cycle engines, compared with four-cycle, was due to loss of charge in the exhaust, as Professor Hopkinson stated. He thought it due chiefly to the fact that the effective stroke of a two-cycle was less than that of a four-cycle. In a two-cycle engine, 22 to 25 per cent. of the stroke was occupied with exhaust and charging. In a four-cycle the whole stroke was available for expansion. He did not think there was any loss through the ports of an Oechelhaüser engine, as air was first injected, then gas, and then further air. This gave some stratification and only air passed through. Another reason why there was a loss of efficiency in a two-cycle engine as compared with a four-cycle, was that two-cycle engines as at present constructed employed charging pumps, and these required work to drive them. Professor Hopkinson had referred to the waste of charging air. He (the speaker) did not look on this as an unmixed evil. If one worked things too closely, back-fire became possible. Some time ago Messrs. Beardmore had experimented on this point, and had reduced the loss until it was touch and go as to whether they got a back-fire. They now purposely arranged that some of the charge of air should go straight through. All the same, he was not impressed by an engine recently brought to his attention by the inventor, in which 50 to 60 per cent. of the air went into the exhaust, the inventor remarking that air was cheap.

The theory put forward and work done by Professor Hopkinson might be useful to designers, but he would like to criticise some of the methods used. In hearing of the care taken in analysing the samples of cylinder content he was reminded of the man who evaluated some quantity as 1.004 and got the 0.004 correct all right. Professor Hopkinson had measured the air by means of a diaphragm. To measure a large quantity of air was a tricky business, and he should like to have seen the result checked by a Venturi meter, or in some such way. It was suggested in the paper that the result might be right to within 3 per cent. He was inclined to suggest that this might be made 30 per cent. Again, he thought the method of taking the samples of gas for analyses not likely to lead to accurate results. The sampling-bottle was in constant connection with the cylinder, so that the quantity of material entering it at any time must have been proportional to the pressure. A disproportionate quantity must have got through at explosion. He suggested that a timing-valve should have been fitted and samples trapped at different parts of the stroke. Another point was that when a charge first enters the cylinder, it was expanded by the heat of the walls, so that the charge in a given volume was reduced. Then Professor Hopkinson had assumed the pressure in the cylinder during admission to be that of the atmosphere, but in some two-cycle engines one had a plenum in the cylinder at that time. To get over loss of charge in the exhaust he suggested that a sort of constriction might be introduced into the combustion-chamber, so that the incoming air would converge and drive out the products of combustion with little mixing.

Turning to the Fullagar engine, he would like to congratulate Mr. Fullagar on the remarkably simple appliance he had produced. He (the speaker) felt flattered that the Oechelhaüser principle had been adopted. He said this without any jealousy, since as far as his firm (Messrs. Beardmore) were concerned, the Oechelhaüser engine was dead. They would not build any more. This was not because the engine was not reliable. Two of their works were driven entirely by it. If the engines stopped, the works stopped. But the engines did not stop. He liked the double-acting cylinders of the engine and the absence of gland packings. By way of criticism, he might point out that the two cylinders of a unit were interdependent. If anything went wrong with either, both stopped. Another thing was that the two side rods of a pair were not the same. They were not interchangeable. A third point was that the construction made it impossible to carry the ports all round the cylinders; some were blocked off. He thought this a disadvantage, as the ports all round were a considerable help towards obtaining stratification.

Mr. E. Hall-Brown said that, in view of the short time available, he would make his remarks very brief. Apart possibly from the method of obtaining the samples of gas, he could see nothing that could be criticised in Professor Hopkinson's work. The theory of design was most valuable. No one had worked out even the basis of such a thing before, and designers had had nothing to go on. This could be seen in the very different sizes of scavenging-cylinders put in by different makers to do the same work. He had not yet had time to study Professor Hopkinson's paper thoroughly, but felt deeply indebted to him for it. The information in reference to the giving up of the manufacture of Oechelhaüser engines by Messrs. Beardmore, given by Mr. Stokes, was very interesting, but it was a pity the meeting had not been told the reason for it. [Mr. Stokes here interposed to say it was simply because the engines proved too costly to build.] Turning to the Fullagar engine, Mr. Hall-Brown said he thought the form of cylinder adopted, which eliminated all possibility of cross-strains, was an admirable point. The engine was very simple, but he would point out that in the diagram shown in the hall and included in the paper the scavenging and gas-supply pumps were not shown. These would, of course, make it appear rather more complicated. He would like an expression of opinion as to the probable efficiency of a Diesel engine built on the same lines. As a final point he might say that it was a moot question as to the size of gas-engine piston it was necessary to water-cool, and the cooling of the four pistons of a Fullagar engine would be rather a complicated job.

The Chairman, in winding up the discussion, said he thought the outstanding features of the Fullagar engine were its simplicity and the absence of initial strains and unknown stresses. In Diesel engine-building most of the difficulties were due to unknown stresses, due to high temperatures. The balancing of the Fullagar engine seemed to be excellent, judging by the way it ran. This should

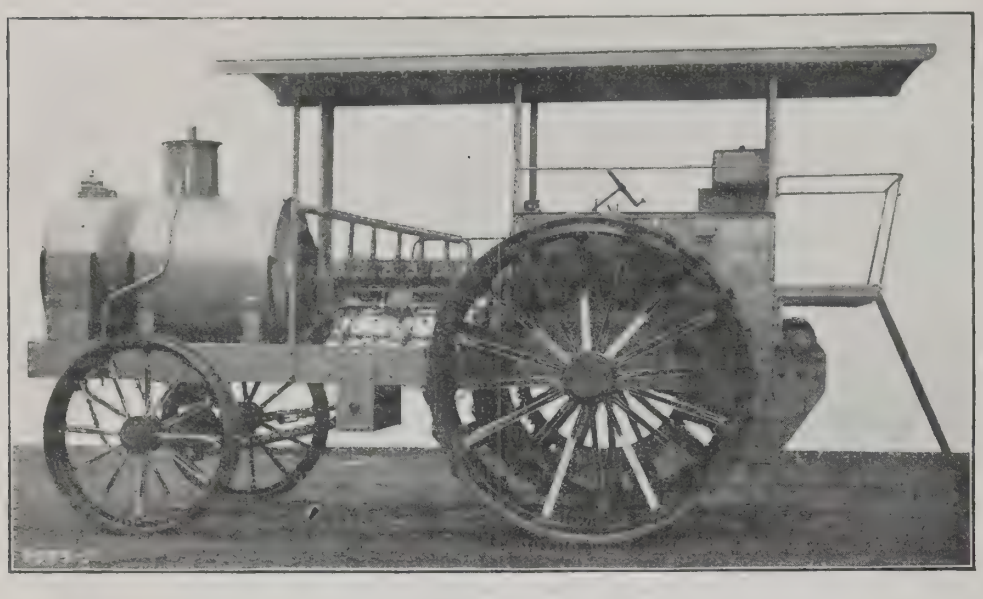

FIG. 1.

FIG. 2.

add to the life of the main bearings, which in a Diesel was frequently remarkably short. The meeting was most indebted to Professor Hopkinson for his valuable paper. He had done to their Institution a great honour in reading it before them. Needless to say, Professor Hopkinson's name was a household word, and they were all indebted to the valuable work carried out at Cambridge.

Professor Hopkinson, in reply, said it was always a pleasure for him to come to Newcastle, and he never left without having learnt a good deal. He had seen much of the Fullagar engine over six months, and at one time had pretty well lived with it for several days, and no one could do that without realising that it represented an important development. The engine at present was running on coal-gas, and it was possible trouble might arise when it was tried on tarry gases, but Mr. Fullagar was working on the question. He thought the engine a very important contribution towards the solution of the big-gas-engine question. A gas-engine with large cylinders seemed in a way against nature; the weight of the cylinders went up in proportion to the diameter, and the thick layer of gas radiated proportionately more heat to the cylinder walls. He thought it fair to say that few people had tackled the big-cylinder gas-engine without dropping money. To make a large-power gas-engine, and to make money at the same time, it seemed necessary to go in for a lot of cylinders, like the National Company, who fitted twelve. About 22 in. seemed to be the limit for cylinders without water-cooling, but with a large number one got a very large number of parts, valves, &c. The Fullagar engine could apparently be built with a large number of cylinders and still require only a moderate number of parts. This seemed to him to make it an important contribution to the big-gas-engine question

In conclusion, he would like to make a brief reply to Mr. Stokes's remarks on his paper. Mr. Stokes thought the loss in two-cycle cylinders was due to loss of stroke. No doubt there was something in this, but he would point out that his idea was in harmony with his work on the Fullagar engine, in which there was no loss of gas in the exhausting, the exhaust-port being practically closed before the charge entered. Mr. Stokes spoke of his measurement of the air by a diaphragm method, and suggested that the pulsations would make the result inaccurate. He thought he had made it clear that the pulsations were damped out by the large air-receiver. He really thought that he might claim an accuracy of more than 30 per cent. for his work. On the question of the method of taking the gas samples he admitted the matter was a difficult one, and that a timing-valve might have had advantages. All the same, he thought his procedure gave fairly reliable results, as reliable as the rest of the work done in the engine. One might at times get a certain amount of stratification, but it did not matter what one got in any particular sample as long as the average was correct. He thought, perhaps, Mr. Stokes had misconceived the object of the paper, and he was grateful to Mr. Hall-Brown for his remarks. All he wished to do was to initiate a method of design for two-cycle engines. The method might be sound—in general he thought it was; but, finally, of course, it must stand the test of experience.

Mr. Fullagar then replied very briefly to the discussion. He said the only difficulty they had had in connection with the running of the engine was caused by the long pipe connecting the air-receiver with the cylinder. This caused differences of pressure. The trouble was difficult to locate, but had been quite done away with. The matter was dealt with in Professor Hopkinson's paper. The meeting then adjourned.

DIESEL ENGINE EXPERIMENTS.

On Friday, the 10th inst., the technical meetings were resumed at 10 A.M., in the Lecture Theatre of the Literary and Philosophical Society. Three papers, submitted by the Institution of Engineers and Shipbuilders in Scotland, were down for reading and discussion. Dr. R. T. Moore, President of the Institution of Engineers and Shipbuilders in Scotland, was in the chair. In the course of some preliminary remarks thanking the North-East Coast Institution for their hospitality during the summer meeting, Dr. Moore suggested that an alliance between the two Institutions might be of value to both. The Institutions were interested in the same classes of shipbuilding and engineering activity, and an alliance involving common proceedings would enlarge the sphere of utility of the papers presented to both, and would have other attendant advantages. Dr. Moore then called upon Mr. W. S. Burns to read his paper entitled "Some Experiments on a Diesel Engine."

The paper dealt with some trials carried out by the author on a Diesel engine in the Mechanical Engineering Laboratory of the Royal Technical College, Glasgow. The subject of the trials was suggested by Professor Mellanby, and they were carried out as a research by Mr. Burns while holding a Beilby Scholarship. The trials were made with the object of discovering the effects of: (1) Variation of blast pressure; and (2) variations of jacket-water temperatures, on the running of a Diesel engine. In order to study the combustion part of the cycle more easily than was possible from an ordinary indicator-card, a rotary-card arrangement was fitted up, which greatly extended the length of the diagram. Many characteristic indicator-cards were given in the paper. The results of the experiments on blast pressure showed that on light loads the excess air in the cylinder and the inrush of blast air with a small quantity of fuel caused late ignition and slow combustion. As the load increased and the mixture of pulverised fuel and air became richer, there was earlier ignition and an increase in the rate of propagation of the explosion. At all loads, too low a blast pressure pulverised the oil imperfectly, causing late ignition and incomplete combustion, with increase of exhaust pressure and temperature above the normal. Too high a blast-pressure caused late, but violent, ignition, attended, again, by incomplete combustion. The general results of the jacket-water experiments showed that at all loads increase of jacket-water temperature did not seem to affect the point of ignition of the oil appreciably, but caused more rapid and more complete combustion with increased efficiency.

Professor A. L. Mellanby opened the discussion. He was asked to speak by the Chairman in the absence of volunteers among the audience. Professor Mellanby said that he had not intended to contribute to the discussion, and was rather surprised that no one had risen to criticise some of the methods described in the paper. The work had really been undertaken out of curiosity, owing to differences which had been noted in the working of the Diesel engine as the blast and jacket-water temperature varied. The ordinary indicator diagram showed very little of what was happening, owing to the record of pressure changes being crowded into such a small space, and the rotary diagram arrangement described in the paper had accordingly been devised. The opened-out diagram had taught them a good deal, and showed, for instance, that the ordinary text-book explanation, that the injected oil burned at constant pressure, was not accurate. Variations in the blast pressure made great differences, and in all cases there seemed to be a short period in which the oil did not burn, and during which the moving forward of the piston caused an increase of volume, and consequent fall of pressure. After this fall of pressure the oil seemed to ignite, giving a sudden explosion. It was usual to put this sort of effect down to inertia of the indicator, but he could not think that was the explanation in the present case. Frequently the explosion could actually be heard. The charges due to alteration in the blast pressure were well brought out in the diagrams, but it must be remembered that the results in any particular case would depend on the type of fuel valve and pulveriser used.

Professor R. L. Weighton, the next speaker, said the paper was concerned with a type of work well suited for research by a student. The results reflected great credit on Mr. Burns. There was one point to which he might refer, which was

FIG. 1.

FIG. 2.

FIG. 3.

brought out in Table II. of the paper. It would be seen that in Experiment 11 an increase in the temperature of the inlet jacket-water was accompanied by an increase in the temperature of the exhaust. In Experiment 12, however, the reverse was the case. He would like to know if this was correct, as the reason did not seem clear. He would also like to know what effect increase of temperature had on mechanical efficiency. If increased cylinder temperature meant increased economy, it would be easy to get economy, because it was easy to get temperature. The matter was important, and it would be interesting to know what the allowable limit of temperature was. A higher temperature meant saving in jacket-water, which was frequently of great importance. He supposed one could not well raise the jacket-water above the limit of vaporisation.

Mr. Summers Hunter asked if the experiments were all carried out with the same quality of oil.

Mr. J. T. Milton said that, like Mr. Summers Hunter, he wished to know something more about the oil used. In the analyses of the exhaust gases which were given in the paper there was no mention of hydrogen, which was practically always present. All the paper gave in reference to the oil was its specific gravity and its net calorific value, and these did not give any proper idea of its character. The viscosity of the oil at higher temperature was a most important point and might greatly affect the results. An analysis of the oil showing the hydrogen present should certainly have been given. Professor Mellanby had spoken of explosions in the cylinder. He did not believe any such effect properly took place. The matter was one of rapid combustion. Another point was that in many cases combustion did not seem to have been perfect, as carbon monoxide was present in the exhaust.

Mr. W. S. Burns, in reply, said that the point raised by Professor Weighton was to be explained by the fact that in Experiment 13 there was more efficient combustion of the fuel. The question of the oil raised by Mr. Summers Hunter and Mr. Milton was dealt with fully in a paper on "Oil Fuels," in the Transactions of the Institute of Engineers and Shipbuilders of Scotland, vol. lvii., page 195. The reference was given in his paper. Mr. Milton had further pointed out that there was no mention of hydrogen in the analyses of the exhaust gases which were given. These analyses were taken by engineers, and the results were not given in the detail which a chemist would perhaps have used. In general traces of hydrogen only were found—0.02 per cent. at most.

OXY-ACETYLENE WELDS.

The next paper was by Professor A. Campion and Mr. W. C. Gray, and was entitled "On the Strength of Welds made by the Oxy-Acetylene Process." It was read in abstract by Mr. Gray. We hope to reprint the paper later.

Mr. J. T. Milton was the only speaker on the discussion. He said that he believed certain governing bodies had at length recognised oxy-acetylene welding as a proper method of repair for boilers and other important structures. For himself, he entirely agreed with the final remarks in the paper to the effect that autogenous welds always represented a somewhat uncertain quantity, and there was no means, except by destructive tests, of ascertaining whether a weld was good or bad. This idea was consistently acted on by Lloyd's. They had, and still, refused to accept autogenous or oxy-acetylene welding for repairs, which, in case of failure, would result in possibility of serious damage or danger to life. For repairs in which failure would not involve serious consequences, he thought such welding very satisfactory and convenient, and it was accepted by Lloyd's.

For the shell-plates of boilers and such like repairs, for which it was recommended to them, however, they could not accept it. People had even suggested repairing crane parts in this way, and sticking together broken crank-shafts. Where tightness was required rather than strength, the system was admirable. The only point in reference to the paper he would mention was that all the experiments described had been carried out on comparatively small pieces, and that if large pieces had to be dealt with, it would be much more difficult to get uniform welds. He was afraid large welds might frequently show inferior results. Lloyd's had accepted oxy-acetylene welding for large parts in temporary repairs. There was a

case of a steamer at Messina at the time of the earthquake. Her stern-frame was broken, and was welded on this system. It seemed to have been a thoroughly good job, and apparently might have been left in. The owners, however, preferred a new frame, and the repaired one was taken out when the boat got home.

Mr. Gray, in reply, said that it had been the original intention of the authors to make some large welds and test them in tension, but the large college testing-machine was being used in connection with the work on gun-metal, which formed the other paper to be presented that morning.

This third paper was entitled "Influence of Various Temperatures on the Properties of Admiralty Gun-Metal." It was by Professor J. G. Longbottom and Professor A. Campion. In the absence of both authors the paper was taken as read, and the meeting then terminated.

PRESENTATION OF FREEDOM OF NEWCASTLE-ON-TYNE TO SIR CHARLES PARSONS.

The City Council of Newcastle-on-Tyne, on March 4 last, passed a resolution to confer the honorary freedom of the city upon Sir Charles Parsons, "in recognition of his distinguished services in the cause of science, particularly in the invention and development of steam-turbine engines," and on Sir Joseph W. Swan "in recognition of his distinguished services in the cause of science, especially in the inventing and perfecting of electric lamps and improvements in photographic processes." It was decided to defer the formal presentation to Sir Joseph Swan in the hope that he might be sufficiently strong to come to Newcastle in the summer, and also to postpone the formal presentation to Sir Charles Parsons until the meeting of the Naval Architects in the city. To the great regret of all, Sir Joseph Swan died before the formal ceremony could take place, but it was decided that the minute of the Corporation containing the resolution, printed on vellum, should be handed to Lady Swan and his family at the same time as the conference of the freedom on Sir Charles Parsons, and accompanying the formal resolution was a service of plate. Mr. Kenneth Swan, son of Sir Joseph Swan, in peculiarly appropriate terms, acknowledged the presentation. Sir Charles Parsons was presented with a silver-gilt casket, containing the document on which was engraved the formal resolution. The Lord Mayor, in making the presentation, and Sir Charles Parsons, in acknowledging it, appropriately reviewed the incidents connected with the development of the steam-turbine. Sir Charles was in a reminiscent mood, and acknowledged the assistance which he had received from many workers in connection with scientific work, and the encouragement and financial assistance from others in the development and application of the turbine.

THE DINNER OF THE INSTITUTION: BATTLESHIP *versus* SUBMARINES.

The guests attending the conference were entertained to dinner on Friday evening by the North-East Coast Institution of Engineers and Shipbuilders. Sir Charles Parsons presided, and the loyal toasts having been honoured, the Earl of Durham made the announcement that the King had consented to be patron of the North-East Coast Institution of Engineers and Shipbuilders. His lordship afterwards submitted the toast of "Our Royal and Merchant Navies."

Lord Charles Beresford, in reply, contributed what was practically a speech on the paper read by Sir John Biles at the inaugural meeting of the Congress on the protection of battleships against submarine attack. Referring to the controversy regarding the relative efficiency of surface and submarine vessels, he said that the discussion was not at all inopportune, but he thought that on this occasion it was unwise to jump to hasty conclusions.

Submarines and air vessels were no doubt new and most important auxiliaries in naval warfare, but at present he thought they must count these new forces more in the nature of defence than attack. Danger existed to our Navy and to the navies of other nations from submarines and aircraft, but no war was without danger. Whenever a new danger appeared, it was their duty to meet it and beat it. They had heard theories before, and many of the gentlemen present had, by their knowledge, energy, and enterprise, manufactured what was wanted. Referring to the ram, torpedoes, and mines, Lord Charles said he was always opposed to the ram. He wanted a straight stem to knock in the side of the other ship. He thought it would be foolish to cease building battleships because a new auxiliary of attack or defence had appeared in all countries. They must never forget that a French Minister went crazy over the torpedo-boat and destroyers, and for many years the French nation was displaced from the position of a first-class naval power on account of a fad. The submarine, Lord Charles continued, could only operate by day and in clear weather, and it was practically useless in misty weather. The submarine could not see the object it was going to attack. It must come to the surface to see; and because of its very limited vision it must come close to its object before it could fire its weapon, and when on the surface it was visible for miles. A machine-gun or a few bullets would put it out of action. It could not defend itself, and a great limitation was the time it could remain under water. Then there was the great anxiety as to whether they were going to sink a friend instead of an enemy. There was no means of communication with a submarine. We were going to have, it was stated, a new British tradition, a new British doctrine—that the fleets had to remain in harbour because there was some danger at sea. Our old tradition was that when we heard of a danger we at once went out to meet it. The idea of remaining in harbour was entirely foreign to the characteristics of our race. The true lessons of war in naval campaigns were never to run away from a danger. Wars were always won by attacks, and never by defence. Hard practical facts must be thought of as well as theories. How would he suggest the danger of the submarine should be met? He would meet it in two ways. He would build a sufficient number of small craft and speedy torpedo-destroyers and small cruisers, and he would keep round the fleet circles of these vessels. When a submarine came to the top, these craft would be on it as a whale-hunter would be on a whale. In the second place, he thought the naval architect was quite capable of armouring the under-water parts of ships, as proposed by Sir John Biles, to protect battleships against torpedoes, without greatly affecting other tactical qualities. They could not afford to gamble with experiments in regard to the defence of the Empire. The superiority of the submarine had not yet been proved in either peace or war. The fundamental principle of strategy at sea remained with the surface fighting-ships, and the battleship must remain the unit of naval defence at present. Lord Charles referred to air-craft as enormously useful both ashore and afloat as scouts, and paid a glowing tribute to the mercantile marine, pleading for better recognition for their "brothers of the sea."

Principal Hadow, of Armstrong College, proposed the toast of "The Guests," to which the Lord Mayor of Newcastle, Sir John Biles, and Dr. R. T. Moore responded. The health of the Chairman was proposed by Sir George Holmes, and Sir Charles in reply paid a thoroughly well-merited tribute to the thoughtfulness and organising ability of the Secretary of the North-East Coast Institution, Mr. E. W. Fraser Smith, on whom a large part of the success of the meeting depended. In some of the arrangements he had the co-operation of Mr. R. W. Dana, the Secretary of the Institution of Naval Architects, and Mr. E. H. Parker, the Secretary of the Institution of Engineers and Shipbuilders in Scotland. All three, and the Reception and Executive Committees at Newcastle, have the satisfaction of knowing that the arrangements made provided for all contingencies, and that the proceedings throughout the whole week were an unqualified success.

105 H.-P. AGRICULTURAL TRACTOR.

IN the account of the Royal Agricultural Society's Show at Shrewsbury, in our issue of the 3rd inst. (page 20 *ante*), we made mention of two tractors shown by the Daimler Company, Limited, Coventry. One of these, of 105 brake horse-power, we illustrate on page 78, in Figs. 1 and 2, showing respectively a side and end view of the machine. This powerful machine, capable of exerting a draw-bar pull of from 10,000 lb. to 12,000 lb., is mounted on four wheels, the leading pair being 5 ft. in diameter, with faces 1 ft. 2 in. across, while the main wheels are 8 ft. in diameter and 3 ft. 9 in. across the face. This tractor weighs about 12 tons. It is fitted with a six-cylinder sleeve-valve engine, with cylinders 150 mm. bore by 150 mm. stroke. All engine parts are lubricated by a multiple plunger-pump. The engine is started by means of a small single-cylinder auxiliary air-cooled engine which is first started up. The transmission from the main engine is through a cone clutch to a gear-box with which is combined the worm and differential gear. The main wheels are driven by spurs and pinions. When ploughing the drive is direct through the worm and main-wheel spur-gears. For higher speeds gears in the gear-box are thrown in. The gear-box gives two speeds (2 and 4 miles per hour) forward and one reverse (2 miles per hour), the engine running at 1000 revolutions per minute. The radiator is of the tubular condenser pattern. The water is circulated by a centrifugal pump driven off the engine. The front portion of the barrel-shaped tank on the machine is the fuel-tank. Air is passed through the radiator-tubes by a large fan driven by the engine. The solid front axle is pivoted centrally. The tractor has been designed for work on a large scale, and is capable of hauling a 14 or 21 disc plough cutting 6 in. deep and 8 in. wide. It will plough $3\frac{3}{4}$ acres per hour. It is also provided with a belt-driving pulley giving a belt speed of 2300 ft. per minute.

FIVE-TON TIPPING TRAILER.

IN our account last week of the Royal Agricultural Society's Show at Shrewsbury we referred to a new tipping trailer shown at the stand of Messrs. Ruston, Proctor and Co., Limited, of Lincoln. We now give, on page 79, illustrations of this trailer, which will afford a more adequate idea of its construction. This wagon is constructed to Constable's patents. In Fig. 1 the wagon will be seen tipped to the off side; Fig. 2 gives a view when tipping to the near side; while Fig. 3 shows the body returned to the normal position. The body is supported by twelve small wheels, four of which are fixed to the chassis and eight (in two lines) to the tipping-body. Channel-section rails are arranged for these wheels to run on. The body is first traversed and then tipped by one continuous movement. A shaft with bevels may be seen on the chassis. This gears with square-threaded screwed shafts running across the chassis. One of the latter is worked by a removable crank-handle, shown in position in Fig. 1. The operation of this crank thus drives both transverse shafts. On each screwed shaft is a toggle, the central pin of which runs in Z-bar rails attached to the tipping-body, while one end of the toggle has a screwed nut working on the shaft, and the other an idle nut sliding on the transverse shaft. To each idle nut is attached an upright lug, and as the flattened toggle is traversed across the chassis when the screws are turned, these lugs push the body over until they come to the far side of the frame. As soon as the traverse is complete, the sliding-nut can move no further, and the toggle closes up, causing the body to tip.

On the chassis in Fig. 1 will be seen two inverted stirrup-irons. The body tips about a centre formed by the kinks in these irons, in which are caught the pins of two of the carrying-wheels. The body tips to an angle of 40 deg. To return the body, the screwing movement is reversed, and the toggles are flattened out. Their central pins, running above the Z-bar ledges or rails, pull the body down, and when returned to the horizontal the same pins come into contact with stops on the rails, and pull the body over. The tipping gear is in duplicate, so that the body can be tipped on either side, always being worked from the opposite side. It is only necessary to turn down two stops on one side or the other before tipping. In the figures it will be seen that a horizontal rail runs across either end of the wagon, and that under this rail are hooked the ends of levers attached to the side doors which run the length of the wagon. As the body is traversed, the hooks of the door-levers come under this rail, and when the traverse is converted into a tipping movement, the doors are prevented from falling with the body. They are thus automatically opened, as shown in Fig. 2. Each door is fitted with four wedges, which engage and disengage of their own accord in sockets on the body. The doors are hinged to the side and flap outwards. The wagon is a one-man affair. Its tare is 52 cwt. and its load is 5 tons. It is made, however, in sizes up to 10 tons capacity. The wagon illustrated can be tipped in $1\frac{1}{2}$ minutes from starting the traverse. The load is deposited without shock to the wagon and well clear of the wheels, &c.

LOCOMOTIVE FOR THE P. L. M. RAILWAY.

IN 1894 the Paris, Lyons, and Mediterranean Railway Company placed in service, especially for the Paris to Marseilles main-line goods traffic, a 0-8-0 type of locomotive capable of hauling a load of 782 tons at a speed of 36 km. (22.37 miles) per hour. This class was followed in 1907 by a heavier design of the 2-8-0 type, scheduled to handle 1177 tons at a similar speed. The continued growth of the traffic has since rendered another development necessary, the demand being for a class of engine capable of hauling 1300 tons at a speed of 45 km. (28 miles) per hour. This has been met by the design of a class of 2-8-2 four-cylinder compound locomotive, of which we give drawings in Figs. 1 and 2, on Plate XV., with this week's issue of

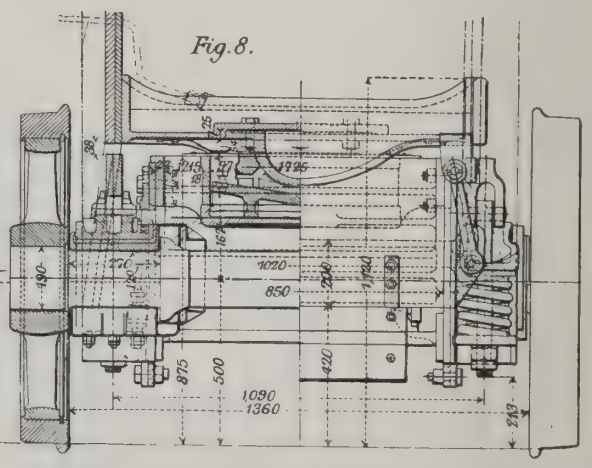

Fig. 9.

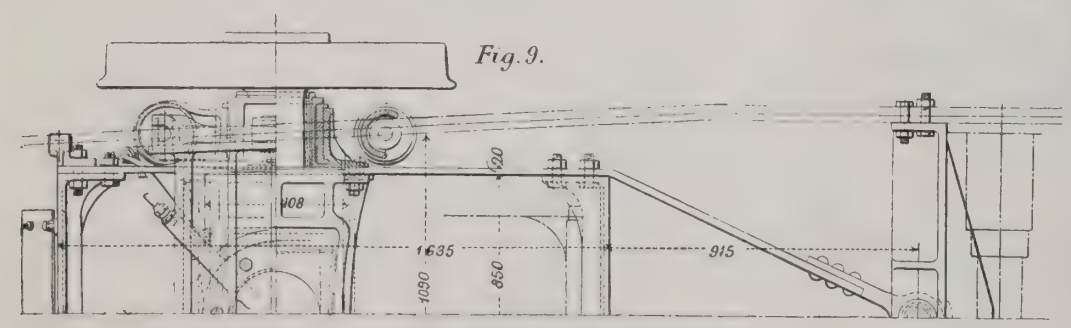

ENGINEERING, and in Figs. 3 to 12, on pages 81, 82, and 83. One of these locomotives, to the designs of Mr. L. Marechal, is to be seen at the Lyons International Exhibition. Of our figures the first two represent respectively an outside and a sectional elevation of the locomotive. Fig. 3 is a cross-section through the cylinders and smoke-box; Fig. 4 is an end elevation of the cab; Figs. 5 to 9 are details of the leading and trailing two-wheeled trucks; while Figs. 10 to 12 illustrate the construction of the tender.

The locomotive is of the compound type, with two inside high-pressure cylinders, 510 mm. (20.08 in.) in diameter and of 650-mm. (25.6 in.) stroke, and two outside low-pressure cylinders 720 mm. (28.35 in.) in diameter and 700 mm. (27.56 in.) stroke. The engine is also fitted with a superheater, as it is intended for long-distance traffic, while its coupled wheels are 1.65 m. (5 ft. 5 in.) in diameter, instead of the 1.50 m. (4 ft. 11 in.) of the earlier classes, with a view to making it more suitable for fast timing.

The boiler, except for the fire-box, which is of copper, is of mild steel. The fire-box is of the wide pattern extending over the frames. The fire-box shell is joined directly to the boiler barrel, and is formed of three plates. The fire-box crown is stayed to the shell by hollow steel stays. The upper part of the shell is stayed by a row of transverse stays of steel, drilled at either end for a length of 194 mm. ($7\frac{5}{8}$ in.). The fire-box is stayed to the shell across the water spaces, &c., by manganese-bronze stays. The tube-plate is connected to the barrel by means of ten steel palm-stays. The barrel is composed of three rings. The longitudinal seams are butt joints with double cover-plates, the transverse seams being double-riveted lap-joints. The fire-box door is arranged to hinge horizontally and to open inwards towards the fire-box. It is composed of three sections,

TENDER FOR LOCOMOTIVE (2-8-2 TYPE) FOR THE P.L.M. RAILWAY.

Fig. 10.

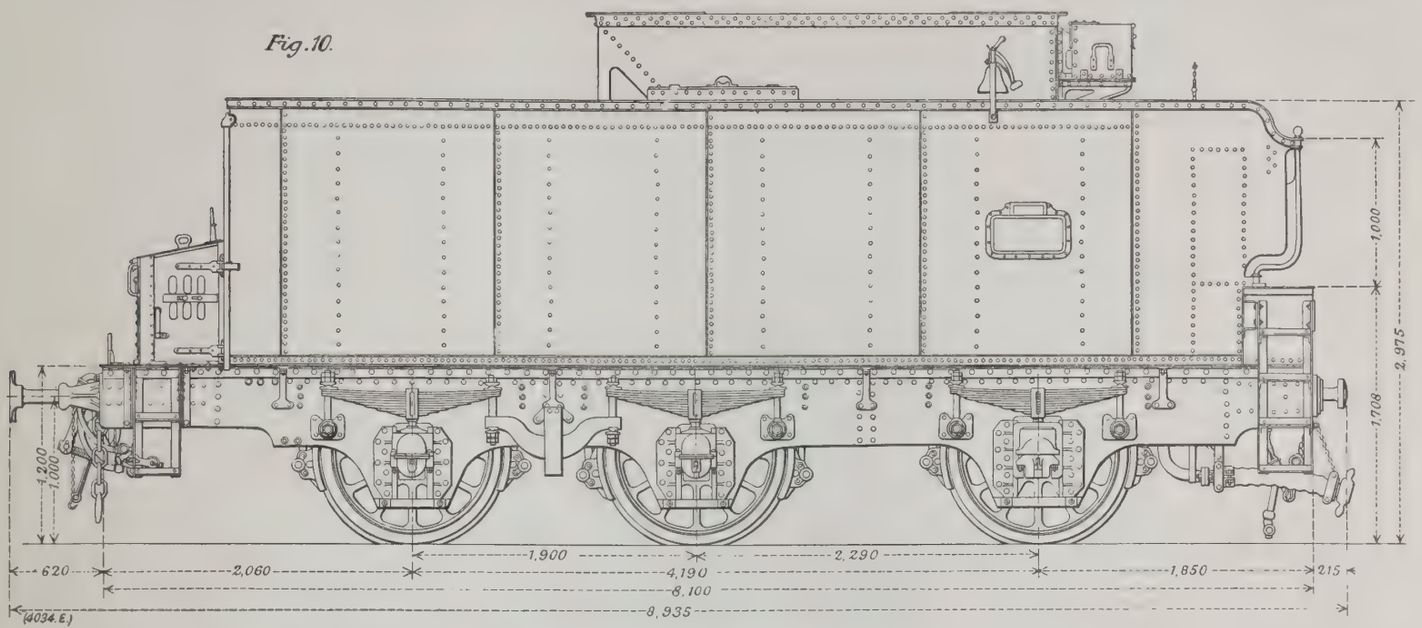

Fig. 11.

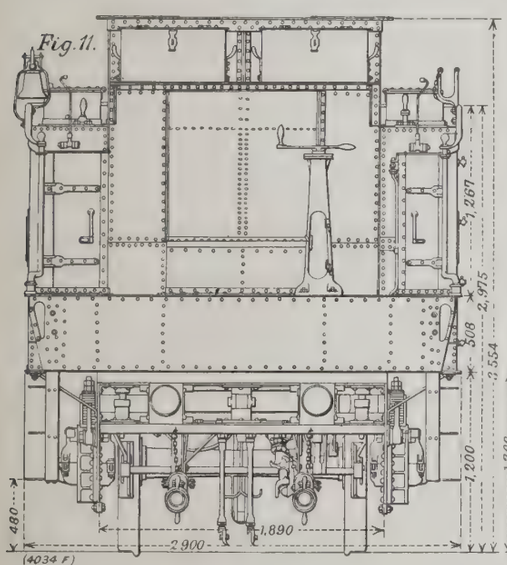

Fig. 12.

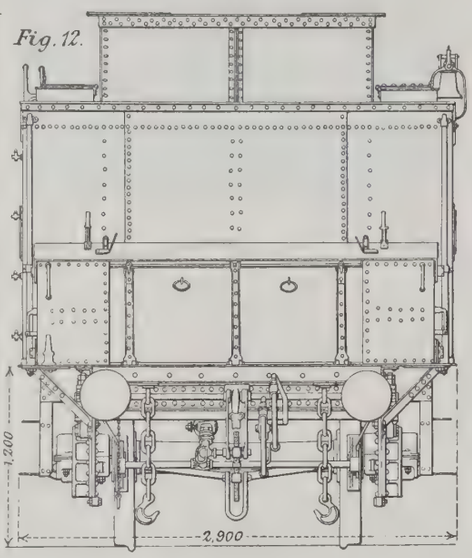

of which the two outside are operated by separate levers. The central section overlaps the other two, so that when either is worked the central one is also operated. Counterweights are provided sufficiently heavy to keep the door open, but not heavy enough to prevent it closing automatically in the event of a boiler-tube bursting. The superheater is of the Schmidt type.

The frames are of steel plate 28 mm. (1.1 in.) in thickness. They are stayed transversely by the leading buffer-beam of rolled I section, a box-shaped stay of plate and angles at the back end, by the inside cylinders, and also by eight intermediate stays of cast steel. The high-pressure cylinders drive on to the second coupled axle, the low-pressure cylinders driving on to the third. The outside cylinders are as large as could be adopted with the existing loading gauge, and the stroke of these cylinders was increased so as to bring the volume into correct relationship with that of the high-pressure cylinders. The cylinder proportions have been chosen with a view to the engine giving maximum power—that is, utilising all the steam the boiler can produce, at a speed of 60 km. (37.28 miles) per hour, instead of the 85 km. (52.8 miles) per hour of the previous class. The running gear, however, is designed so that a speed of 95 km. (56.23 miles) per hour can be maintained with a proportionately lighter load. The pistons are of cast steel, with forged-steel piston-rods. The cross-heads are of cast steel, with cast-iron slippers and white-metal lining. The slide-bars are of hard forged steel, of a tenacity of 55 kg. per sq. cm. (35 tons per sq. in.), and an elongation of 20 per cent. The connecting and coupling-rods are of steel, with brasses lined with white metal.

The high and low-pressure valve-gear is of the Walschaert type. Piston-valves with inside admission are employed. In the reversing-gear, the reach-rods of both the high and low pressure cylinders are brought to a single-screw frame in the cab. On the reversing screw works a screwed cross-head, to which the high-pressure reach-rod is connected. There is, in addition, a floating frame with pins, to which the low-pressure reach-rod is connected, this frame being moved by the high-pressure screwed cross-head, just referred to, after the latter has moved a certain distance. There are only two stable positions for the low-pressure gear—namely, in forward or back gear—but the high-pressure gear can be adjusted at will. A dash-pot arrangement, consisting of a cylinder containing a liquid, in which moves a piston pierced with holes, is provided for the low-pressure gear, the piston being connected with the reach-rod by means of levers. This is necessary, since the floating frame is not fixed to the screw-gear, and when reversing while running the low-pressure gear would be liable to fly over suddenly. The throttle is of the equilibrium type, from which steam passes to the Schmidt superheater of 28 elements. The blast-pipe is furnished with an adjustable cone top.

The leading and trailing two-wheeled trucks are illustrated in Figs. 5 to 9, page 82. The leading truck is built up of two steel castings, one forming the frame for the axle-boxes, and the other the radius-bar. The radius of the truck is 2.150 m. (7 ft. 0.64 in.). An horizontal helical control-spring is provided to return the truck to the central position. The extreme side movement allowed to the truck is 40 mm. (1.58 in.). Hardened-steel plates working in guides on the top of the truck-frame casting over the axle carry the spring load. The truck springs are equalised on both sides with the leading coupled axle. The trailing truck shown in Figs. 7 to 9 is built up of steel castings with steel plate radius-frame. The radius in this case is 1.900 m. (6 ft. 3.8 in.). The load in this instance is carried by the truck on the central sliding casting fitted with cup and ball, the latter being attached to a cross-bearer on the main frame. This centre is provided with crossed inclined surfaces, making the truck self-centring.

The axles are hollow. The axle-boxes are of cast steel fitted with bronze bearings lined with white metal. The horn-blocks are of cast steel with cast-iron liners. The engine is fitted with both the automatic air and the Westinghouse-Henry brakes, the latter giving direct non-automatic applications. The four-coupled axles are braked to 66 per cent. of the axle-load. In addition the cylinders are arranged for counter-pressure braking by reversing. A cock is provided in the cab for use in this connection, for admitting hot water from the boiler into the high-pressure exhaust, and another for admitting steam and water to the exhaust of the low-pressure cylinders. The cylinders are provided with the usual by-pass.

The tender, which is coupled to the engine above described, is, as already stated, illustrated by Figs. 10 to 12, on the present page. It was constructed by the Société Anonyme les Ateliers de Construction du Nord de la France, at Blanc-Misseron (Nord). It has steel frames 20 mm. (0.79 in.) thick. The wheels are 1.200 m. (3 ft. 11.24 in.) in diameter, with outside bearings. The axle-boxes of the leading journals are of cast steel furnished with wedge-plates and slippers, which allow a lateral displacement of 35 mm. (1.38 in.). The boxes of the middle and trailing axles are of cast iron. The horn-blocks of the leading wheels are of cast steel; in the other cases they are cast iron. The springs of the middle and trailing axles are equalised. The tender can accommodate about 6½ tons of coal. In order to provide room for this without stacking it too far back on the tank, the bunker sides are raised above the water-tank. If it is necessary to carry more than this, the fuel supply can be increased to 8 tons by stacking briquettes at the front end of the bunker. The tender is braked with two blocks on all wheels.

The following are the chief particulars of this engine and tender :—

Engine :

High-pressure cylinders (two inside), diameter	510 mm.	(20.08 in.)
Low-pressure cylinders (two outside), diameter ...	720 ,,	(28.35 ,,)
High-pressure cylinders, stroke	650 ,,	(25.6 ,,)
Low-pressure cylinders, stroke	700 ,,	(27.56 ,,)
High-pressure piston-valves, diameter	240 ,,	(9.45 ,,)
Low-pressure piston-valves, diameter	360 ,,	(14.17 ,,)
High-pressure valves, maximum travel	212.5 ,,	(8.36 ,,)
Low-pressure valves, maximum travel	126 ,,	(4.95 ,,

Exhaust maximum opening	0.0237 sq. m.	(36.7 sq. in.)
,, minimum ,,	0.0150 ,,	(23.25 ,,)

v. Tube-cleaner
w. Foot-step
x. Back ash-pan damper handle

CRACKS IN STEEL PLATES.

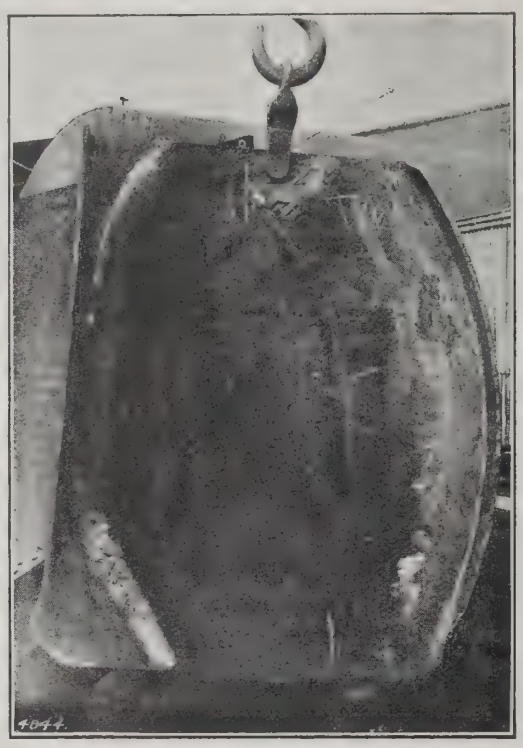
To the Editor of Engineering.

SIR,—I enclose a photograph taken about seven years ago from a tube-plate in course of manufacture for a marine boiler. It will be seen that the plate had gone through the first operations of forming the flanges to take the wrapper-plates of the combustion-chamber. It is one of several others which had been flanged on the same day, and it had been placed to one side with them in a stack. Shortly after starting up on the following morning a loud report was heard to come from the stack of plates, and on examination this plate was found to have cracked in two places. One crack is shown by the white line at the bottom towards the right near to the wood chock, and the other by the similar line near to the clamp to which the crane is hooked.

The plate was subsequently struck a few sharp blows with a heavy wood-flanger's mallet on the side reverse to that shown in the photograph, and out of curiosity as to whether the cracks would extend or others develop. The plate was then lifted, and to my astonishment I found the interesting, and, I believe, unique strain diagram which a careful examination of the photograph will reveal. The white lines at the cracks and all of the innumerable fine lines over the area of the plate are the clean grey steel surface of the plate showing between the overlying blue scale.

The whole area of the plate was apparently under a state of extreme stress, and the effect of the hammer-blows was apparently sufficient to increase the stress beyond the elastic limit, so that the material stretched in many directions, and the brittle scale broke. The measure of the extent of the stretching is the width of the lines, and varied perceptibly, the directions of the stresses are normal to these lines.

It will be noticed that at the edges of the plates, in way of the cracks, the white line is imperceptible. This is because there was no stretch at the edge, the material having broken short, but as the cracks extended inwards the material had stretched very markedly, and so increased the surface of grey steel exposed to view. Taking cross-sections through the plate across the cracks the reduction of thickness or area of section was very perceptible, and where it was greatest it was easy to make an impression upon the steel by means of a sharp knife-blade, but at the extreme edge of the plate where the cracks started the steel was as hard as glass.



The photograph is a poor one, and I much regret that a shower of rain prevented me obtaining a better record of the most beautiful stress diagram I have seen.

At about the same period my attention was drawn to a serious crack in a shell-plate for a large boiler, and which was revealed in a curious manner. The holes had been drilled, and when examining the quality of the work it was noticed that a minute piece of steel had broken off the edge of one hole. Further examination discovered a crack extending right through the plate and from the edge of the plate, across the hole, and for several inches into the plate. But for the chance of drilling the hole right across the crack it might not have been discovered until a very serious accident had happened.

Yours faithfully,

May 29, 1914. R. J. N. W.

[The cracks were somewhat difficult to follow in the photographic print we received, and although great care has been taken in the reproduction, they are still less visible in the engraving.—ED. E.]

WHAT IS HARDNESS?

To the Editor of Engineering.

SIR,—I have noticed that from time to time discussions have arisen, particularly in England, in regard to what hardness is and is not, and also as to what the different hardness-testing instruments show and cannot show. These have been somewhat misleading in the past, for two reasons: Firstly, lack of technical knowledge of the subject on the part of the discussionist; and secondly, the disparagement of one form of testing apparatus in order to advance the sales of another competitive device.

As in everything else, an erroneous discussion, while it often awakens new thought, can just as well mislead, and thus delay progress. It appears to have done the latter in England, for the statistics show that this country is fourth in the line of progress in the adoption and application of the hardness test. In a recent issue of a monthly journal issued by a firm of machine-tool makers, the following statement, among others, is made: "Testing of hardness is full of difficulties, the reason being that the word is used to cover a number of very different properties in materials."

As a matter of proof for these different properties, the relation of the resistance to cutting or machining is discussed. The writer goes on to say that different hardness-testing instruments show different properties. The scratch test, according to him, measures resistance to scratching, not necessarily hardness. The scleroscope, which depends upon the principle of the rebound of a small diamond-face drop-hammer after causing a permanent set in the metal after dropping from a certain height, he says "measures mainly what might be called bounceability," substantiating his claim by the fact that india-rubber, wood, and brass can cause a higher rebound than soft steel, while the Brinell machine measures the resistance to deformation. This, he considers, is the most correct test, although he does not claim that the test will show resistance to cutting in all materials.

Let us first ascertain the relation between hardness and resistance to cutting. Hardness at the present time is generally understood to be a state of rigidness in a body which imparts to it the power to resist penetration and necessarily also deformation. Hardness in metals is much like the integrity of their melting-points, when pure. Fusion, then, always occurs at a fixed and known temperature. This will, however, change with the addition of impurities or by alloying with such metals as may have a higher or lower melting-point. The tendency, then, is for a mutual adjustment between the two, so with the hardness of the metal in relation to its resistance to cutting or machining. A pure metal will show resistance to machining directly in proportion to the increase of hardness.

It does not matter what instrument is used to measure this so long as it indicates resistance to penetration, such as the scleroscope, and also the Brinell machine, when properly operated, does. But this uniform increase of resistance to cutting will only hold good when the clearance of the tool is perfectly adapted to the hardness of the metal; if it is not, all experiments will be misleading. This is, in fact, the first point necessary to understand in the practice of testing for hardness—to determine cutting qualities.

In dealing with alloys, complications necessarily arise, yet a simple rule holds good. The power required to remove chips will depend upon the tensile strength which is developed by any alloy. This is also indicated approximately by the hardness reading. Wear of the tool here is quite another thing, for this depends upon the hardness of the hardest particles in that alloy. The cutting-tool must scrape against these, which are therefore determining factors from the standpoint of tool wear.

A very good illustration of this point is a mechanical mixture of lead and emery. The emery does not impart greater tenacity and therefore physical hardness to the lead, so that it would still be possible to cut large chips therefrom with a steel tool with little power, but in a very short time this tool must wear out because of the grinding action of the emery. This illustration is rather crude, but serves the purpose quite well, and, in fact, may be used as an analogy describing the resistance of different alloys to machining or cutting with steel tools.

Let us first consider mild-carbon steel. This, of course, is an alloy of carbon and iron. Carbon can only combine with iron to form a carbide, Fe 3C, or cementite, which is a definite compound of considerable hardness and has a carbon content of 6 67 per cent. Pure iron then acquires an affinity for this carbide, so that if the total carbon is very low, it appears as a network of mere streaks. These streaks become more numerous as the carbon content increases. Hence, in machining mild steel, the tool is obliged to overcome the tensile strength of the iron and carbon alloy; while the edge, in scraping against the microscopic streaks of hard carbide, will be worn in proportion to the number of these that are contained in the steel. The wear of the tool is then almost directly in proportion to the total carbon content, if it is in the annealed condition, while the power required to remove the chips, as before stated, may be in proportion to the tensile strength or true physical hardness.

A very interesting example illustrating this point is the resistance to cutting offered by high speed steel, which has usually a low carbon content, but yet a high tensile strength, and therefore high hardness reading. The tungsten and chromium with which the iron is alloyed appear to impart hardness, and, therefore, strength, without the formation of gritty material, such as carbide of iron is, for, as we have seen before, this contains 6.67 per cent. of carbon. High-speed steel thus may be 50 per cent. harder than the carbon steel in the annealed state, and while it may take more power to cut, will not show nearly so much wear on the tool, just because the carbon content is lower, the number of carbide grains being less. It is said that these grains are as hard as hardened high-carbon steel; in fact, hard enough to scratch feldspar.

Another illustration of tool failures due to wear, independent of the hardness of the material, is found in the working of wrought iron containing slag grains. A drill may keep going all day without resharpening so long as no slag is encountered; while, on the other hand, it may fail at once if slag is struck, for this impurity is much harder than any hardened steel. It has been found that in connection with cast iron, silicon, which readily combines with iron, and is then easily cut, may be oxidised during the process of melting, and thus turn into particles of silica or stone. These do not impart greater strength or hardness to the iron, for the mixture is purely mechanical; but when an attempt is made to cut the iron having such impurities, the power required to do this is equal to the hardness of the iron, while the wear on the tool will be in direct proportion to the amount of silica or grit it contains.

Another very interesting illustration of this phenomenon is seen in manganese steel. This material usually shows a high resistance to wear at a low physical hardness, and this is evidently due to the fact that it contains particles of great hardness suspended in a cement medium, quite soft and ductile. Consequently such steel cannot be machined by any scraping action. This is because the hard particles, being harder than the tool, quickly scrape off the edge. A cold chisel, however, which has its scraping action reduced to a minimum, will easily cut into manganese steel, the resistance of which is quite exactly in proportion to its physical hardness. This phenomenon teaches a very valuable lesson, and shows how important methods of cutting are with regard to action, shape, and clearance of the tool.

There is another factor which enters into the cutting of

material which has greatly baffled many who have sought to gain the many advantages contained in the hardness test. This is the susceptibility to mechanical hardening under pressure. Let us take, for example, a brass casting 15 hard. This casting, by rolling or hammering, may readily acquire a mechanical hardness of, say, 40. The difference in resistance to machining here cannot invariably be expected to be in direct proportion to the initial hardness. The reason is very simple.

In machining such a casting, it can readily be understood that since pieces have to be cut or torn off, enough pressure must be used to overcome its elastic limit and ultimate strength. This will be great enough to cause considerable mechanical hardening, not only of the chip but of the area from which it is separated. Hence the power required will be greater than indicated by the initial hardness of the casting. The difference will be least where the tool has the greatest clearance, and where so little resistance is therefore offered to the cutting of the chip that but little mechanical hardening can result. As the tool becomes dull or more blunt, the casting will be more and more difficult to machine, not alone because the tool is not sharp, but also because the hardness of the casting will be raised practically to its limit—viz., 40 hard, for the sample selected. If the same casting, however, were first cold rolled, the power required to remove the chips would be in proportion to whatever hardness it was cold rolled at, provided, of course, the form or clearance of the tool is well adapted to the metal. There would be little difference between the initial casting and the same when cold rolled so far as the abrasive effect on the tool is concerned, for, as stated before, this would depend upon the hardness of the hardest particles of the alloy.

It is needless to discuss here the effect of speed, where the principal destructive factor is heat. The theory of hardness has been rather well explained under Professor Howe's analogy of the brick wall, where cement is used to unite the bricks on the one hand, while on the other no cement is used, the bricks being merely piled up to form a wall. The bricks in each wall are of the same hardness. The wall with the cement, which combines the bricks into one unitary mass, is capable of resisting deformation and penetration, and would therefore be considered a hard body, while the one without the cement, under the same mechanical forces, would collapse; therefore it is incapable of resisting penetration and deformation; and although its grains or particles are just as hard, it would be said to have a low physical hardness. We have seen that the cement medium in a body, therefore, is just as important as the particles which it unites.

In addition to hardness of these particles, their shape has much to do with mechanical properties such as those of metals and materials. The analogy of builders' sand and quicksand may here be taken into consideration. The former has sharp angles and surfaces, while in the latter the particles are roundish, and the sand is therefore incapable of supporting heavy weights. This indicates that friction between the crystals and the cement media is a very important factor, and, in fact, the trend of metallurgical investigation at the present time is in this direction, under the science of metallography and microscopic study of structure. When these are used in conjunction with the hardness test, there appear to be a few problems remaining between that test and its practical application, although it is more frequently necessary to use only a little common-sense in addition to the observation of the simple rules given in the foregoing.

I feel that when the readings of the scleroscope are compared with indiarubber in order to disparage that instrument in the eyes of the unwary, it is particularly unfair, for, as pointed out before, no hardness test can be made until permanent set can be caused, and it is certainly not possible to do this in india-rubber with either the scleroscope or the ball test.

The principle of the scleroscope was originally discovered as a result of mathematical studies of the law of conservation of energy. We may have differing opinions as to what relation elasticity may have to hardness in solid bodies; but, according to this doctrine, we can easily see that when a weight is lifted to a certain height against the force of gravity, work is done upon that body equal to the product of the weight by the distance lifted. When this body is allowed to fall again, this work is transformed into energy of motion; and when the body strikes an obstacle, the act of stopping the body causes it to give up its energy of motion, resulting in deformation or breakage and heat. Should, however, this body fall upon another one that is immovable, and that cannot be penetrated or deformed in any way, the energy of motion is not given up, but continues to remain in the falling body as energy of motion, meaning that in an absolute vacuum and absolute freedom from friction it will have to rebound as high as it fell, and thereafter keep vibrating almost for ever.

Under ordinary conditions, the rebound from such very hard materials is less than from the height it falls, because of the resistance of air and mechanical friction; and while the falling body keeps vibrating for a considerable time, the energy of motion is gradually converted into heat due to said mechanical and air friction.

Naturally, since the law of conservation of energy is so extremely exact and persistent, it would necessarily follow that the slightest deformation that can be caused between these colliding bodies will instantaneously detract from the rebounding effort, because of the work that had been done, until at last, when a soft metal, such as lead, is struck, practically all the energy of motion is converted into work, and the most insignificant rebound occurs. The scleroscope, therefore, is an instrument of strictly scientific origin. It obeys the laws of physics, and is deliberately designed toward that end. A properly-conducted hardness test by any correctly-designed instrument, like anything else, must necessarily become valuable, and more and more indispensable, as we learn not to waste time expecting the unreasonable.

In this connection I wish to take this as my opportunity to refer to oft-repeated unfair statements that the size or mass of the piece under test by the scleroscope cause variations of its hardness. It is perhaps needless here to refer to the manufacturers' regular instructions and provisions in the instrument design to clamp minute pieces so that they acquire the inertia of the heavy-enough clamp. In this manner hardened steel and softer metals, as thin as writing-paper, or rods less than $\frac{1}{8}$ in. in diameter, are regularly and faithfully tested.

In common scleroscope practice it is rather fortunate that when little pieces of metal are thus clamped or mounted for testing, the sound of the little drop-hammer will instantly warn the most careless operator as to the accuracy of his operations. When the clamping is satisfactory, so that the small piece has the same inertia as the large mass of the clamp, a dull thud is heard, or the note of a body that size. Smaller bodies have higher or shriller notes, and in order to be sure the clamping has been satisfactory, these must be subdued to correspond to that of the larger body. Only the most ordinary judgment is required to note these sounds, and the operator is therefore guided quite unconsciously.

Yours truly,

ALBERT F. SHORE.

"HYDROSTATIC CATENARY."

TO THE EDITOR OF ENGINEERING.

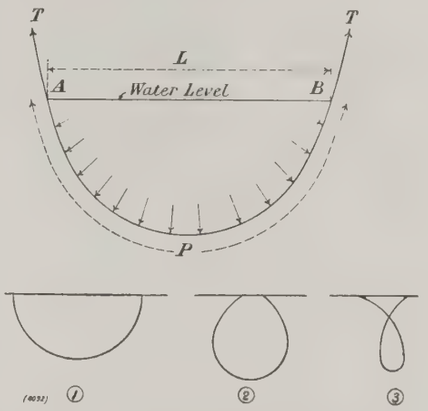
SIR,—I shall be much obliged if, through your columns, I can get a solution to the "hydrostatic catenary."

A flexible sheet, with no resistance to bending, of length P, is hung between two level supports A and B, distant a length L apart, and is then filled with water up to the level of A and B.

1. What is the equation to the curve or catenary in which the sheet hangs?

2. What is the relation between L, P, and T and the maximum ordinate?

3. What area does the curve enclose?



The pressure from the water is everywhere normal to the surface of the sheet, and hence the tension T is constant all round length P for any particular case.

The curve is the same as that assumed by a long column of uniform cross-section under an excessive load. This curve may take various forms in the general case as shown, but it is only case 1 which is used in practice. This section is a common one in light metal flumes for carrying water, and it has been adopted as the water section in a large reinforced-concrete aqueduct at present under construction.

Yours truly,

H. M. GIBB.

Irrigation Department, Brooks, Alberta, Canada, June 29, 1914.

"THE SUBSIDENCES IN THE STREETS OF PARIS."

TO THE EDITOR OF ENGINEERING.

SIR,—As an engineer and a reader of your valuable paper, and who, besides, has been in charge of the shield process of Berlier's Tube from 1906 to 1909, I note in your article "The Subsidences in the Streets of Paris" various points which I take the liberty of taking up as not being quite correct.

1. The line Villiers-Gambetta does not run parallel to No. 1. This line, called "No. 3," intersects the Nord-Sud at St. Lazare, not the Concorde, and runs through the highest level at Opera.

The second level is line No. 7 from La Villette-Opera, joining there No. 8, which runs to Auteuil, crossing the Seine below the Concorde Bridge, and again at Mirabeau, making a half circle on the left bank.

The third and lowest level is the new line, nearly completed, and going to the Palais Royal down the Avenue de l'Opera.

The line where the accidents were crosses No. 1 in the Champs Elysees.

Also, when the Seine invaded the works during the winter 1909-10, the flood came by the Nord-Sud, owing to the breaking of a big sewer running along Boulevard St. Germain, and which was not repaired in time, the tube being completed under the Seine.

The "Berlier Tube," as such was called the "Nord-Sud," was, contrary to your article on June 26, done by the shield under the Seine between the two stations "Chambre des Deputés" and "Concorde," and though great difficulties were experienced from subsoil, as rock was only found right under the river, it turned out a pretty good success for that method, but, except for that portion, all the remaining was done in masonry in the shape of *voûte surbaissée* or *anse de panier*, which was reckoned as being the one giving best results.

As to the stability of the whole, it is a known fact, though it has been criticised, that provided the masonry is made of good material, and thicknesses adhered to, no fears of collapsing can be entertained.

Hoping you will excuse me for interfering so on your time, but thinking it right to mention the above, leaving you to use it as you like.

I remain, yours very truly,

HRY. J. DE CORDEMOY,
Director of the Australian Section,
British Chamber of Commerce, Paris.

Paris, June 29, 1914.

[We thank our correspondent for his corrections, but we think he has not in all cases read our article quite correctly. We wrote, on page 840 *ante*:—"The line No. 3, now completed, is at the lowest level underneath a steel viaduct which carries, at the Place de l'Opéra, the line No. 2. This line No. 3 is known as the Villiers-Gambetta line, and follows a direction generally parallel to line No. 1; it intersects both the 'Nord-Sud' line and the central line which serves the Place de la Concorde, running thence to . . ." Line No. 1 is practically a straight line from the Place de la Bastille to the Porte Maillot, some 4½ miles. Line No. 3 starts at Père Lachaise and runs by the Place de la Republique, the Bourse, the Opera, the Gare St. Lazare, and the Avenue de Villiers to the Porte de Champerre. The two lines are equally distant for about one-third of their length at each end, but for the middle third are somewhat nearer together. It is, however, quite reasonable to describe them as generally parallel. At Gare St. Lazare line No. 3 intersects the Nord-Sud, and here we have evidently mistranslated the original article, which should read: "it intersects the Nord-Sud, which serves the Place de la Concorde." This point was made clear by the map in our second article on page 879 *ante*. The respective levels of the three lines intersecting at the Place de l'Opera are clearly shown on our two-page plate, published on July 6, 1906. No. 3 line is the uppermost.

We have expressly pointed out, and have shown in the drawings, the intersection at the Champs-Elysées of the broken line with No. 1. The inundations at St. Lazare in 1910 were not caused solely by the Nord-Sud, but also by the actual flow of the subterranean water of the subsoil; that is, we believe, accepted. As a matter of fact, M. Berlier constructed the two passages under the Seine with a shield, but the tunnels of the Nord-Sud were, as our correspondent says, built without shields.—ED. E.].

INFLUENCE LINES.

TO THE EDITOR OF ENGINEERING.

SIR,—An expression useful for working out influence lines for a girder divided into a large number of equal spans is as follows:—

Let A B, B C be two adjacent unloaded spans, then by the well-known theorem—

$$M_A l + 2M_B (l + l) + M_C l = 0$$

A	B	C
M_A	M_B	M_C

i.e.,

$$M_A + 4M_B + M_C = 0$$

$$M_A = -4M_B - M_C$$

Now if M_0 = bending moment at the first point of support = 0,

M_1 = bending moment at the second point, &c.

Then the moments at successive points of support until a loaded span is reached are given by—

$$M_n = (-1)^{n-1} \cdot \frac{(2+\sqrt{3})^n - (2-\sqrt{3})^n}{2\sqrt{3}} M_1.$$

Successive values (which are all whole numbers) being

$$M_1, \ -4M_1, \ +15M_1, \ -56M_1, \ \&c.$$

If there are an infinite number of spans—

$$\frac{M_n}{M_{n-}} = -(2+\sqrt{3}) = -3.732.$$

Yours truly,

G. P. MANNING.

102, Fordhook-avenue, Ealing Common, W., July 10, 1914.

P.S.—If you have seen this expression before, please say where it is to be found.

PERSONAL. — Mr. H. G. Humby, M. Inst. C.E., M.I.N.A., formerly consulting engineer to the Natal Government, and subsequently to the Government of the Union of South Africa, having retired, has opened an office at 20, Victoria-street, London, S.W., where he is practising as consulting engineer on matters relating to railways and harbours and their equipment, of which he has had extensive experience.—Mr. H. S. Rowell, A.R.C.Sc., B.Sc., Wh.Sch., has been appointed to the position of Senior Lecturer in Mechanical Engineering at the Bradford Technical College, and will commence his duties in September next. Mr. Rowell had a distinguished career as a student, obtaining successively a National Scholarship and a Whitworth Scholarship in Engineering, a double Associateship of the Royal College of Science (in Physics and in Mechanics) and the B.Sc. (Engineering) degree of London University.

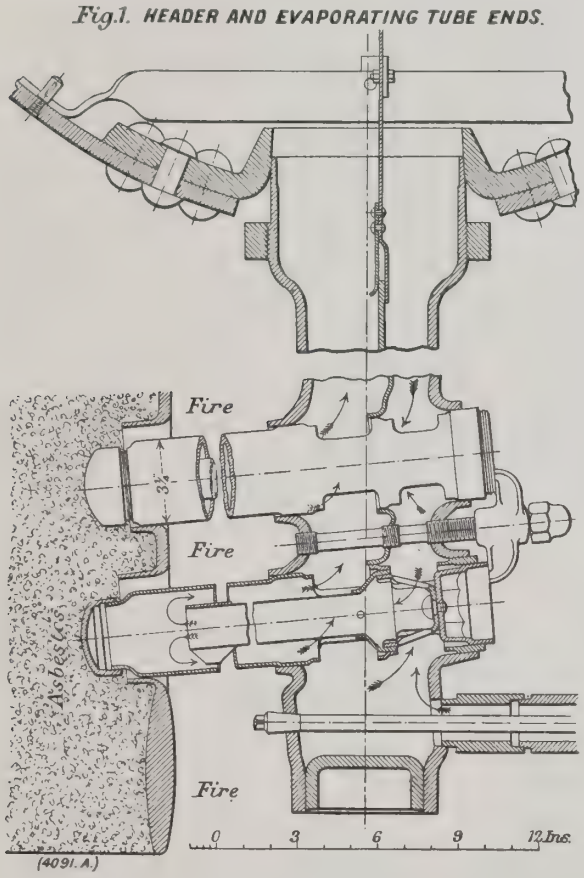
THE NEW NICLAUSSE HIGH-DUTY MARINE-TYPE BOILER.*

By JULES NICLAUSSE, of Paris.

THE Niclausse boiler, of which so many important installations have been made in practically all the navies of the world, in large power-houses, and in industrial factories, is too well known by engineers to require a description, so the author proposes to limit this paper to setting forth briefly the general features and latest improvements.

In the Niclausse boiler all the evaporating-tubes are fitted at one end only into the headers, and a perfectly tight joint is ensured by metal-to-metal conical joints. The other end is closed by a cap, and is carried by a supporting plate. The removal of any tube, either for cleaning or for replacement, is very easily and rapidly effected, so that a shut-down for any cause does not put the boiler out of service for more than a relatively very short time. The tubes being fixed at one end only, expansion or contraction takes place freely, giving complete security against troubles resulting from neglect of this important provision. It will be noticed from Fig. 1, herewith, that the old screwed-on lantern end has been suppressed, the tube being now solid-drawn throughout, with swellings to form the cones.

Fig. 1. HEADER AND EVAPORATING TUBE ENDS.



As shown in Fig. 1, each header is divided into two compartments by a vertical partition plate, separating the steam and water currents. The current of water flowing through the front compartment of the header is distributed to each evaporating-tube by an inner tube contained in the former. Windows cut in the header end of the evaporating tube enable the water to enter and the steam to depart in two distinct currents, so that positive circulation in only one, and that the correct, direction is ensured.

During the last two years, a number of improvements have been made in the details of the Niclausse boiler, without affecting the principles of its operation and construction. Some years ago the malleable cast-steel curved headers were replaced by headers constructed in solid-drawn pressed steel of increased and of rectangular section, and recently the firm introduced a special system of feed distribution to serve the lower tubes, which are those nearest the furnace, and are the principal evaporating tubes. For this purpose the steam and water drums are divided into two compartments by a longitudinal diaphragm plate in prolongation of the vertical partitions in the headers, as shown in Fig. 2; the feed, after passing through a trough C, wherein carbonates and other impurities are precipitated, and whence they are ejected by means of a blow-down valve D, enters at the front compartment, descends the vertical headers for a certain distance determined by a cross diaphragm E, passes into the upper evaporating tubes, and returns with the steam there produced into the back compartment of the drum, which consequently contains only hot and purified feed. The purified feed then descends by two tubes placed in front of the side walls, in the case of the high-duty boiler (see Fig. 3, opposite) into a square horizontal header located longitudinally in front of, and connecting by an elbow to, the bottom of each of the vertical headers.

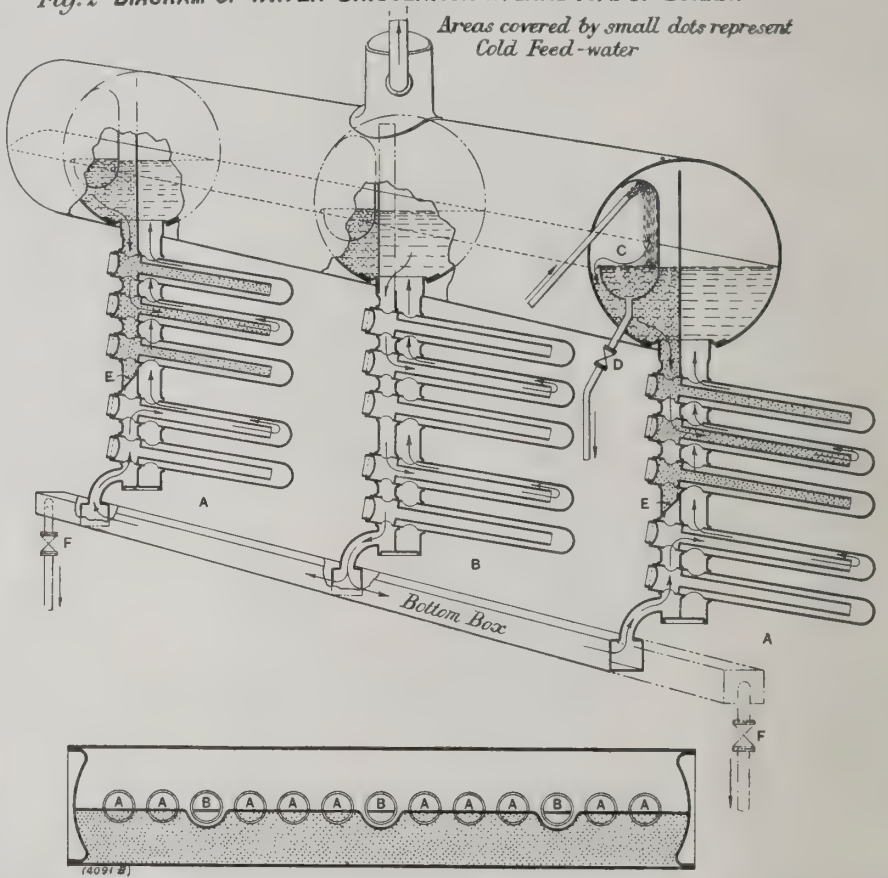
* Paper read before the Institution of Mechanical Engineers, at Paris, July 8, 1914.

The upper tubes are therefore fed by relatively cold feed-water, and the bottom tubes by the purified hot feed. The horizontal header also serves as a "bottom box," Fig. 2, whence impurities can also be rejected by blow-down valves F fitted at each end of it.

The lower tubes, which are most exposed to the heat of the furnace, consequently receive the feed at boiler steam temperature, and free from any impurities in the feed to the upper tubes are practically harmless, since the temperature of the gases surrounding them is insufficient to form a hard scale.

In the modern land-type boilers the system is simplified, without impairing its efficiency, by suppressing the vertical downtake pipes. These are replaced by one header out of every four or five, in which no cross-diaphragm is fitted in its front compartment, so that it serves to feed the "bottom box" and the lower tubes of all the headers fitted with the cross-diaphragm, whilst its own lower tubes are served direct. The arrangement will be quite clear from Fig. 2, A, A being headers having the cross-diaphragm in their front compartment taking impurified feed from the front side of the drum to feed the upper tubes, B being a downtake header taking its hot purified feed-water from the back side of the drum, the division-plate therein being suitably arranged for this purpose, as shown at B in plan.

Fig. 2 DIAGRAM OF WATER CIRCULATION IN LAND TYPE OF BOILER



In the new high-duty marine-type boiler the firm have still further increased the section of the headers, chiefly in the rear compartment forming the passage for the steam. This is about 4½ times larger than in the modern land-type headers. Furthermore, an inclination of 15 per cent. instead of 10 per cent. has been given to the tubes, in order to facilitate disengagement of the steam. Also, the outside diameter of the tubes has been reduced from 84 mm. to 60 mm. ($3\frac{5}{16}$ in. to $2\frac{3}{8}$ in.), a reduction which has been rendered practicable, with complete security against all forms of distress, by the above-mentioned improvements.

The new high-duty boiler is fitted with a feed-reheater placed above the tubes. The water circulates into this apparatus on the contra-flow principle—that is, in the reverse direction to the hot gases. The official tests referred to hereafter show the efficacy of this feed-reheater, as much from the point of view of the feed-water temperature as from that of the chimney-gas temperatures.

The high-duty marine boiler, having no superheater as usually arranged between the tubes in the land type, is fitted with a new system of gas-baffling, which doubles the length of the gas flow in the tube *faisceau*, ensuring improved utility and efficiency. This comprises plain open-ended tubes laid between the evaporating tubes, forming gas-passages, as will be seen from Fig. 3.

All the above improvements were comprised in the test-boiler recently tested by the French Navy experts. Full dimensions of this boiler are given in the Appendix, page 88, and in the drawing showing its general arrangement, Fig. 3. The tests of this boiler by the Committee of Naval Experts appointed by the French Admiralty, and carried out in September last, comprised:—

1. A six-hour trial at the combustion rate of 95 kg. of coal per square metre of grate surface (19.5 lb. per sq. ft.). The evaporation in pounds from and at 212 deg. Fahr. was 13.1 per pound of coal fired, the thermal efficiency being 91.5 per cent., and the capacity 20,000 lb. per hour from and at 212 deg. Fahr.

2. A six-hour trial at the combustion rate of 180 kg. of coal per square metre of grate surface (37 lb. per sq. ft.). The evaporation in pounds from and at 212 deg. Fahr. was 11.5 per pound of coal fired, the thermal efficiency being 79.8 per cent.

3. A 16-hour trial at the combustion rate of 225 kg. of coal per square metre of grate surface (46 lb. per sq. ft.). The evaporation in pounds from and at 212 deg. Fahr. was 11.4 per lb. of coal fired, the thermal efficiency being 79.3 per cent., and the capacity 41,000 lb. per hour from and at 212 deg. Fahr.

4. A 4-hour trial at the combustion rate of 135 kg. of petroleum per square metre of grate surface. The evaporation in pounds from and at 212 deg. Fahr. was 15.5 per pound of fuel burnt, the efficiency being 78.8 per cent.

5. A 5-hour trial, to demonstrate the elasticity of the boiler. Operation took place as follows:—Half an hour at the combustion rate of 95 kg. per sq. metre of grate surface; half an hour at the combustion rate of 180 kg.; half an hour at the combustion rate of 225 kg.; one hour at the combustion rate of 240 kg.; a quarter of an hour at the combustion rate of 180 kg.; a quarter of an hour stop; 10 minutes at the combustion rate of 95 kg.; three-quarters of an hour at the combustion rate of 135 kg. with oil fuel; a quarter of an hour at the combustion rate of 95 kg. of coal. This trial proved that the boiler made the change from these different rates with perfect success, and without any difficulty.

Further tests were made on January 6 last by a party of English engineers. The results fully corroborated those obtained by the French naval experts.

During the No. 3 trials, the percentage of water entrained was at maximum only 0.9 per cent. This was determined by the salt method with the Kennedy apparatus. The maximum temperature of the gases at foot of chimney was only 330 deg. Cent. (625 deg. Fahr.) during the sixteen hours' test at the combustion rate of 225 kg. per sq. m. (46 lb. per sq. ft.) when the evaporation was 105 per cent. above the normal. It must be added that the feed-water used was the ordinary town water, which was not in any way treated or purified, and which during the official tests was subjected to an addition of such a quantity of sea salt as to give 1 deg. of salinity to the water in the boiler. Valvoline was also added in the proportion of 175 grammes per ton of coal fired. On the results of the tests made by naval experts in September last, the French Admiralty placed with the firm an order for twenty-one boilers, aggregating 36,000 horse-power, for the 25,000-ton super-Dreadnought Bearne, laid down on January 1 of this year.

For land service the new high-duty boiler is arranged in much the same manner as in the Niclausse land type, and is fitted with superheater and mechanical stoker, both of the firm's design and make. The superheater is constructed of several serpentine sections interpolated and coupled to two headers, one at the entrance and the other at the steam exit. The serpentines, which are placed within the nest of tubes in the latter, are located above the *faisceau* in the new high-duty-type boiler for land service.

The Niclausse mechanical stoker comprises fire-bars in short sections interlocking with each other and carried in supporting bearers, which are given an intermittent to-and-fro motion, so that two adjacent bars always work in

THE NEW NICLAUSSE HIGH-DUTY BOILER.

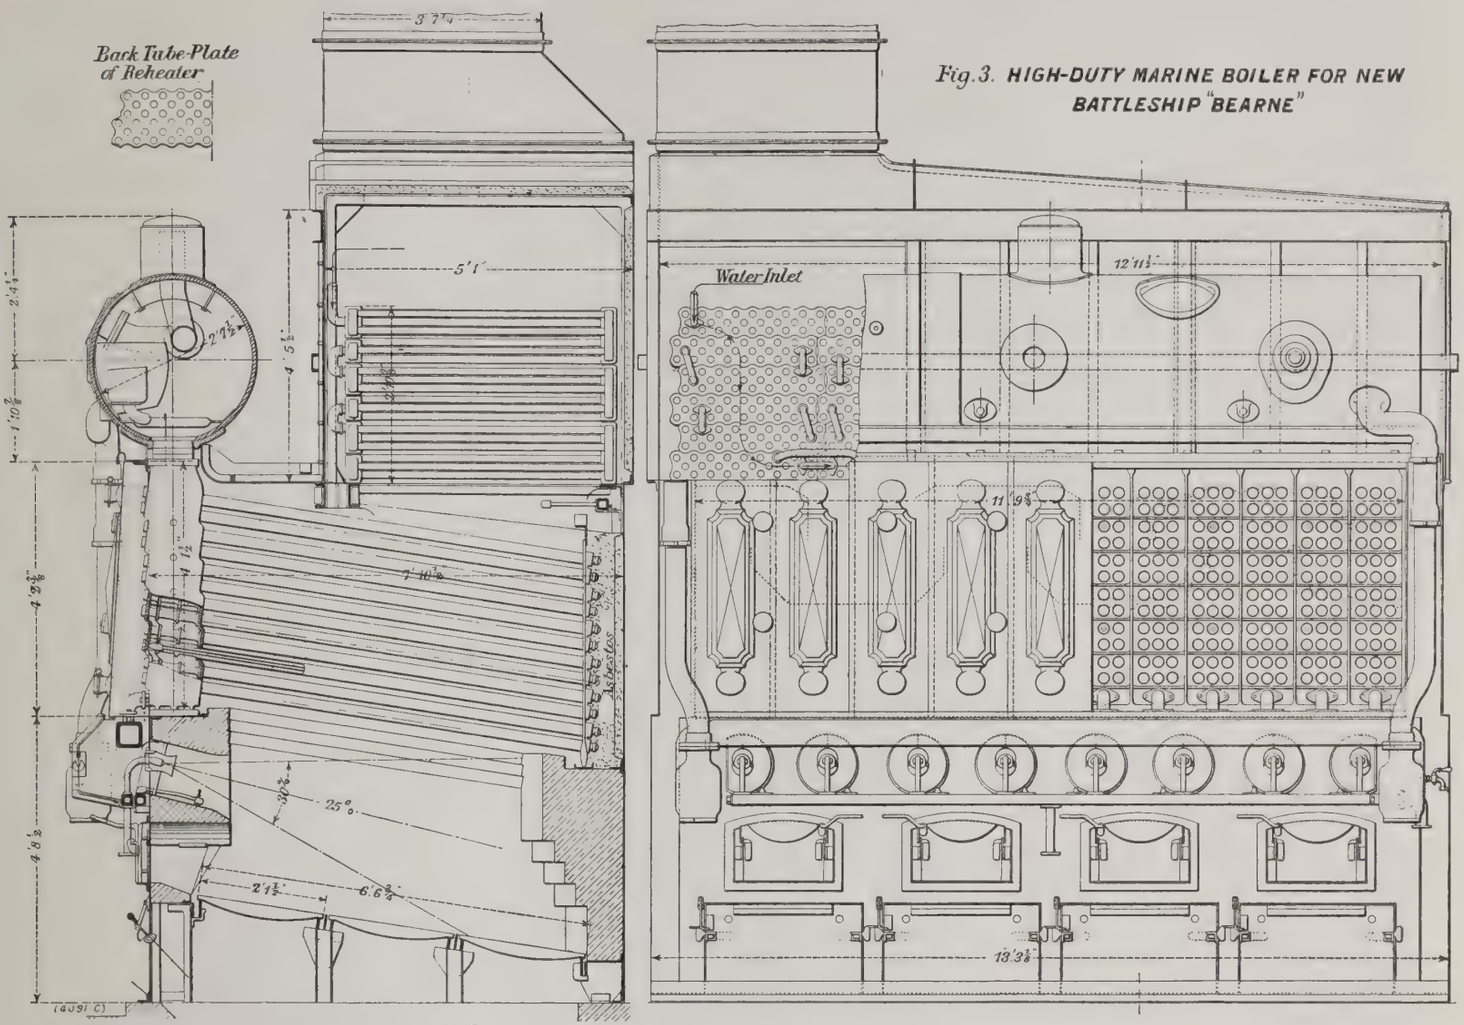


Fig. 3. HIGH-DUTY MARINE BOILER FOR NEW BATTLESHIP "BEARNE"

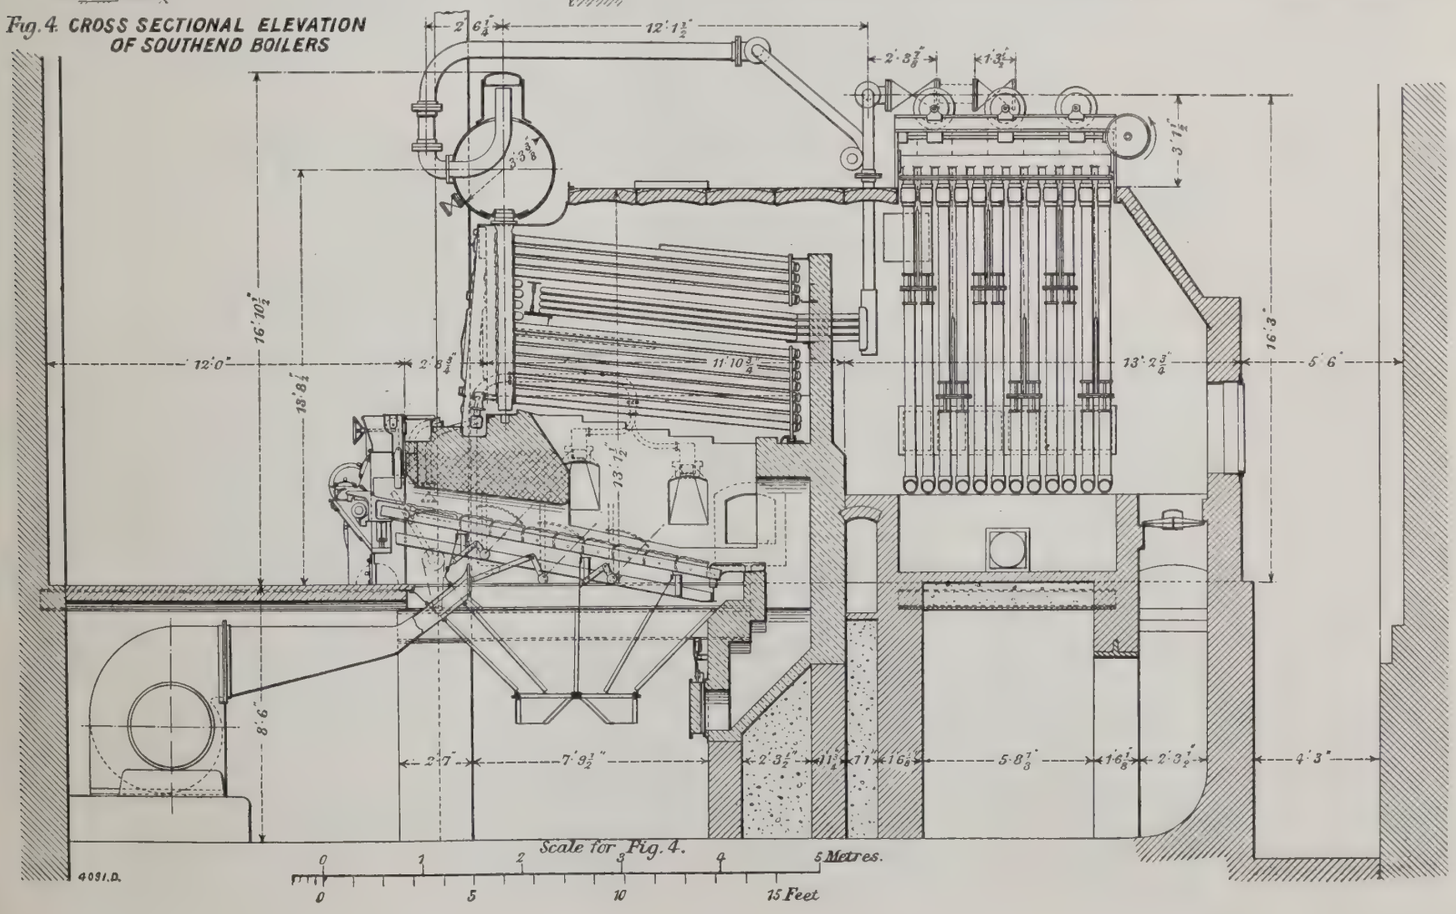
Fig. 4. CROSS SECTIONAL ELEVATION OF SOUTHEND BOILERS



opposite directions. There is a momentary pause between the movement backwards and forwards. The bar movement is effected by means of a slowly-rotating shaft fitted with hard-steel cams, which engage with hard-steel trip-pieces mounted on the bearer-heads. The speed of the driving-shaft can be varied from 1 to 6 revolutions per minute. Below the grate is fitted a series of hoppers serving as both air-ducts and ashpits. The air supply is furnished preferably by a forced-draught fan worked at low pressure, This system is very much more economical than either the induced or ejector-draught systems. The ashpit is divided into three compartments, in which the air supply is regulated independently to the different zones of the fire-bed, whereby perfect combustion with any kind of fuel is ensured. The ashpit compartments also serve to separate green fuel riddlings from the fine ashes, the former being trapped in the front compartment, and the latter in the rear compartment, whilst the clinkers are delivered into a capacious hopper under the end of the grate. The Niclausse stoker, of which there are over 200,000 horse-power at work, has been proved capable of burning all classes of solid fuel, from coke-breeze and coals having only 8 per cent. volatile matter to the coals richest in volatile matters. Recently, it has been tried in England with very high volatile Midland coal, and in South Wales with extremely low grade, low volatile, high ash Welsh coal, with successful results.

Fig. 4 illustrates the arrangement of the stoker, also the superheater, with respect to the boiler, as instanced in the recent installation of two 25,000-lb. to 35,000-lb. per hour boilers, complete with stokers, &c., at the Corporation Electricity Works of Southend-on-Sea, in England.

APPENDIX.

Particulars of the Boiler Submitted for Trials by the Navy.

The general arrangement of the boiler is shown in Fig. 3. Other particulars are as follows:—

Working pressure (gauge)...	18 kg. per sq. cm. (256 lb. per sq. in.)
Number of headers... ...	13
Number of evaporating tubes, upper	300 (thickness, 2½ mm.) (0.099 in.)
Number of evaporating tubes, lower	156 (thickness, 4 mm.) (0.16 in.)
Total number of tubes ...	456
Cleaning tubes	12
Outside and inside diameter of upper tubes, mm. ...	60 × 55 (2.36 in. × 2.16 in.)
Outside and inside diameter of lower tubes, mm. ...	60 × 52 (2.36 in. × 2.04 in.)
Height of headers	2.300 m. (7 ft. 6 in.)
Length of tubes projecting outside the headers ...	2.020 ,, (6 ,, 7¼ ,,)
Number of tubes in economiser	780
Length of economiser tubes (outside headers)	1.216 m. (4 ft. 0 in.)
Length of grate	2 000 ,, (6 ,, 6 ,,)
Width of grate	3.690 ,, (11 ,, 9½ ,,)
Grate area	7.20 sq. m. (77.5 sq. ft.)
Heating surface of outer tubes	...173.62 ,, (1870 ,,)
Heating surface of economiser	...119.22 ,, (1285 ,,)
Total heating surface	...292.85 ,, (3155 ,,)

The ratio of outer heating surface of the tubes (neglecting the header surface) to the grate surface is:—

Outer surface of evaporating tubes...	24.11 to 1
Outer surface of economiser tubes ...	16.56 to 1
Ratio of total heating surface to grate area	40.67 to 1

Space occupied by boiler = 114 sq. ft.; height to top of dome, 13 ft.

Hourly evaporation per square foot of ground space occupied:—

(*a*) At normal load, with rate of combustion of 19.5 lb. per sq. ft. of grate surface = 175 lb. per hour from and at 212 deg. Fahr.

(*b*) At overload, with rate of combustion of 46 lb. per sq. ft. of grate surface = 355 lb. per hour from and at 212 deg. Fahr.

50-FT. MOTOR PINNACE FOR THE BRITISH ADMIRALTY.—A motor pinnace of 50 ft. length, the first of the class, was delivered at Devonport Dockyard during the second week in July by Messrs. John I. Thornycroft and Co., Limited, making the non-stop voyage from Southampton—a distance of 130 nautical miles—under her own power in less than 12 hours. The type is very similar to the 50-ft. steam-pinnaces at present carried on battleships, and is, indeed, destined to replace them. The only important difference between the motor and steamboats is in respect of the machinery. The machinery consists of one Thornycroft S/6 type direct reversible paraffin engine starting on blow-lamp. The cylinders are six in number, 8½ in. in diameter by 12-in. stroke, and the engine develops 150 brake horse-power at about 550 revolutions per minute. The initial impulse is given to the engine by compressed air at 575 lb. introduced through non-return valves on the cylinder-head. The air is stored in three steel reservoirs in the engine-room. Reversing is effected by moving the cam-shaft longitudinally, thus bringing another set of cams into operation. There is a compressor driven by cam-shaft at the fore end of the engine, and also an auxiliary hand-driven compressor for the first charge in the reservoirs.

THE INSTITUTE OF METALS.

THE Autumn Meeting of the Institute of Metals will be held in Portsmouth on September 10 and 11. The meetings will be held in the Portsmouth Municipal College. On Thursday, September 10, there will be a general meeting, at 10 a.m., opened by the official welcome of the Institute by the Mayor of Portsmouth, Alderman J. H. Cooke, and the Chairman of the Education Committee, Alderman F. G. Foster. Afterwards papers will be read and discussed. In the afternoon a visit will be paid to H.M. Dockyard. In the evening a dinner will be held at the Queen's Hotel, followed by a reception by the President, Engineer Vice-Admiral Sir H. J. Oram, K.C.B. On Friday, September 11, in the morning, more papers will be considered, after which members will visit and take lunch at the works of Messrs. J. Samuel White and Co., Cowes. Alternative motor excursions have been arranged for the afternoons—namely, for Thursday to the New Forest or Arundel, and for Friday, to Carisbrooke Castle. The papers to be taken at the meetings will, it is expected, include the following:—"The Wiedmanstättian Structure in Various Alloys and Metals," by Captain N. T. Belaiew; "Ductile Tungsten and its Internal Structure," by C. Gladitz; "Tensile Tests on Copper at High Temperatures," by Mr. D. Hanson and Dr. G. D. Bengough; "The Critical Point at 460 deg. Cent. in Zinc-Copper Alloys," by Mr. O. F. Hudson; "A Note on the Annealing of Brass," by Mr. F. Johnson; "The Deposition of Metals by the Spraying Process," by Mr. R. K. Morcom; "The Effect of Hydrogen on the Annealing of Gold," by Mr. J. Phelps; "A Contribution to the History of Corrosion—Part III., Coke, Condenser Tubes and Corrosion," by Mr. A. Philip; "The Surface Tension of Molten Metals," by Mr. S. W. Smith; "The Behaviour of Copper-Zinc Alloys when Heated in a Vacuum," by Mr. W. E. Thorneycroft and Professor T. Turner.

THE MOTOR EXHIBITION.—At a recent meeting of the Society of Motor Manufacturers and Traders, Limited, the date of the Motor Exhibition at Olympia was fixed for November 6 to 14. From the applications for space received it was manifest that the coming Exhibition would be even more international in character than heretofore, and would demonstrate the fact that Great Britain is the world's market for automobiles.

COAL EXPORTS FROM CALCUTTA.—The exports of coal from Calcutta by sea during the half-year ended March 31, 1914, were 1,614,484 tons, as compared with 1,498,304 tons in 1912-13. For the whole of the year ended March 31, 1914, the exports were 3,036,353 tons, as compared with 3,104,834 tons for the year ended March 31, 1913. The exports to Bombay were 549,961 tons; to Karachi, 230,939 tons; and to Rangoon, 210,223 tons. Of the coal exported in the half-year ended March 31 this year, 1,296,225 tons were carried by the East Indian Railway, as compared with 1,100,688 tons in the corresponding period of 1912-13.

INTERNATIONAL MUNICIPAL CONFERENCE.—The Mayors of some of the most important cities of the United States, together with a number of ladies and gentlemen identified with municipal matters, will arrive in London at the end of the present week, and from Monday, the 20th inst., to Saturday, the 25th inst., will join in an International Municipal Conference at the Anglo-American Exposition, at the White City, Shepherd's Bush, London, W., with Viscount Peel, the Chairman of the London County Council, as President. Amongst the subjects to be discussed are:—The administration of Public Health, including regulations for housing and prevention of disease, and all matters connected with sanitation and sewerage, municipal trading, the supply of electricity, gas, and water by public bodies, and the arrangement for provision and control of traffic. Parks, open spaces, town planning, and recreation. The administration of justice, police, and protection from fire. Control of building operations and destruction of insanitary buildings, with reference to the protection of health and life. Housing, &c. Relief of the poor, hospitals and orphan asylums. Public welfare. Education. Control of licensing, and relation with central government concerning part of the revenue derived from such licences, and the question of subsidy. Care of children; female and child labour.

OFFICIAL FIRE-TESTS.—The British Fire-Prevention Committee conducted two series of fire-tests last week at their Regent's Park testing-station. The first of these dealt with a fibrous material suitable for partitioning and panelling, known as "Calno," which was put before the Committee by the Fireproof Fibre Building Boards, Limited. It was tested in panel form of various thicknesses, the thinner panels for duration and the thicker for the Committee's standard forty-five minutes' test, with a view to obtaining the classification for affording "temporary protection" (Class A). The second series was with a partition and with two doors of non-flammable wood, treated by the Timber Fire Proofing Company, Limited. The partition was submitted to the Committee's forty-five minutes' test, with a view to obtaining the classification for "temporary protection" (Class A), and the 2-in. doors to the one-hour test, with a view to obtaining the classification for "temporary protection" (Class B). The temperature throughout these tests had to range from 1500 deg. to a temperature not exceeding 1650 deg., and the fire-test was followed by the application of water from the steam fire-engine. The results of the tests will be submitted in the form of a report in due course. The next testing-day at the Regent's Park testing-station will be July 22, which will be devoted to a series of three glazing tests, among which will be wired-glass skylights.

NOTES FROM THE NORTH.

GLASGOW, Wednesday.

Glasgow Pig-Iron Market.—Last Thursday morning the pig-iron market was quiet, and Cleveland warrants fell away a little. The turnover was limited to 500 tons at 51s. 4½d. cash, with closing sellers at 51s. 5d. cash, 51s. 7d. one month, and 51s. 7½d. three months. In the afternoon the market was dead idle, the only change being in the prices of Cleveland warrants for the three months position, for which sellers named 51s. 7d. On Friday morning there was little doing, and the only business was one lot of Cleveland warrants at 51s. 4½d. cash, and closing sellers quoted 51s. 5d. cash, 51s. 7d. one month, and 51s. 7½d. three months. The afternoon session was again idle, and no change was made by sellers in the quotations for Cleveland warrants. On Monday morning a good tone prevailed, but buyers were absent, and no dealings took place. Sellers of Cleveland warrants quoted 51s. 6d. cash, 51s. 8d. one month, and 51s. 9d. three months. The afternoon session was also a blank as regards business, and no change was made in sellers' prices. The firmer tone again held good on Tuesday morning, and dealings amounting to 1500 tons of Cleveland warrants were put through at 51s. 7½d. August 25, and at 51s. 9d. and 51s. 8½d. three months. The closing quotations were 51s. 6d. cash, 51s. 8d. one month, and 51s. 9d. three months sellers. In the afternoon Cleveland warrants remained steady, but business was at a standstill. Sellers made no change in their prices, although buyers shaded their's. When the market opened to-day (Wednesday) there was once again little feeling for business, and while the tone was steady, no dealing took place. Closing quotations for Cleveland warrants were 51s. 6d. cash, 51s. 8d. one month, and 51s. 9d. three months sellers. In the afternoon another blank session was recorded, and a holiday feeling prevailed. There was little change in prices, and sellers of Cleveland warrants quoted 51s. 6d. cash, and 51s. 8d. one and three months.

Sulphate of Ammonia.—A firm tone prevails in the sulphate of ammonia market this week, and there has been a little better demand on shipment account. The current price is now 11*l.* per ton Glasgow, and about 11*l.* 2s. 6d. per ton Leith, for prompt lots.

Scotch Steel Trade.—At last the annual fair holidays are with us, and those responsible for keeping the works going are relieved for a little of some of their anxiety. No demand of any moment has been experienced of late, and there has consequently been no pressure for delivery of steel before closing down, except in the case of urgent lots; in fact, some establishments put up their shutters several days earlier than usual owing to the shortage of specifications. The quieter tone experienced in the shipbuilding industry during past weeks, or months, coupled with the inroad of foreign material, has told severely on the demand for the local manufacture of steel plates, &c. Makers of black sheets are also very quiet, and the outlook is really so poor that the holidays will be extended this year. Export orders, while fair, have lately been of rather limited tonnage, and not nearly so heavy as is generally expected at this time of year. Prices show no change, and are called 5*l.* 12s. 6d. per ton for ship-plates, 5*l.* 7s. 6d. per ton for angles, and 6*l.* per ton for boiler-plates, all less the usual 5 per cent. for Clyde delivery or equal.

Malleable-Iron Trade.—No change has to be reported in the state of the malleable-iron trade of the West of Scotland, and now that the holidays have arrived, and the various works are closed, the re-opening will be put off as long as possible unless the horizon becomes clearer. Specifications have been so scarce that work has only been carried on intermittently for some time. Prices are unchanged, and are based on 6*l.* 12s. 6d. per ton for "crown" bars.

Scotch Pig-Iron Trade.—There has been a very poor demand for Scotch pig-iron during the past week, both on home and export account, despite the fact that the present output is much restricted from the normal. The serious crisis which has arisen in the coal trade has hastened the blowing out of furnaces, and since the coal-masters are resisting the limiting by the miners of the coal output of the country, there is the probability of a hard struggle. The success of the miners would have the result of raising the prices of fuel, and if iron-masters find it hard enough to secure business at the present prices, in these days of foreign competition, it is difficult to anticipate what the future prospects of the iron trade may be. The current quotations for makers' (No. 1) iron are as follows:—Clyde, 66s.; Calder, Gartsherrie, Summerlee, and Langloan, 66s. 6d. (all shipped at Glasgow); Glengarnock (at Ardrossan), 70s.; Shotts (at Leith), 66s. 6d.; and Carron (at Grangemouth), 67s. Hematite is very quiet and the demand has fallen away considerably.

Iron and Steel Imports.—The registered imports of iron and steel, during the month of June, into the ports of Glasgow, Grangemouth, Greenock, Leith, Dundee, and Aberdeen, were as follows:—

	Ex-Continent. tons	Value. £	Ex-U.S.A. tons	Value. £
Iron bars, angles, &c. ..	3836	24,996	—	—
Steel bars, angles, &c. ..	1058	6,722	117	887
Iron and steel hoops and strips..	831	5,561	1420	11,190
Iron and steel plates ..	2348	15,270	—	—
Totals	8073	52,549	1537	12,077

NOTES FROM SOUTH YORKSHIRE.

SHEFFIELD, Wednesday.

South Yorkshire Coal Trade.—Not for a long period have the South Yorkshire house-coal pits worked so irregularly. The demand from all classes of consumers has shrunk so consistently that there are scarcely sufficient orders to keep the men engaged for more than three days out of the seven. Even with this greatly restricted output stocks are making an appearance. Prices show an average decline of 6d. Steam hards are firmly held at last week's prices. A heavy tonnage is going into consumption in the steel industries. The shipping demand is gradually approaching the magnitude of twelve months ago, though there is still a good deal of leeway to be made up. Gas-coal is a quieter market. During the last week many of the big consumers who have been holding out for reductions on last year's contract rates have agreed to place renewals at the old figures. Coke is weak, and producers are putting out more furnaces. The outlook in this department is regarded with a good deal of uncertainty. Patent oven coke is being taken on contract at 9s. 6d. per ton. The best market is for steel coke, which makes up to 27s. per ton delivered. Best slacks find a ready sale, but in the lower qualities production is considerably in excess of the demand. Quotations:—Best branch hand-picked, 15s. to 16s.; Barnsley best Silkstone, 12s. to 13s.; Derbyshire best brights, 11s. 6d. to 12s. 6d.; Derbyshire house, 10s. 6d. to 11s. 6d.; best large nuts, 10s. 3d. to 11s. 3d.; small nuts, 9s. to 10s.; Yorkshire hards, 11s. to 12s.; Derbyshire hards, 10s. to 11s.; best slacks, 7s. to 8s.; seconds, 5s. to 6s.; smalls, 2s. 6d. to 3s. 6d.

Iron and Steel.—Consumers of pig-iron are, for the most part, postponing buying, in the expectation of obtaining cheaper rates, and though for several weeks past quotations have produced only the smallest margin of profit, further slight concessions are being made on orders of any bulk. The excess production of coke has so far enabled makers to keep values exceptionally low, and with prices still declining, there is still prospect of further cheapening in production costs. Makers are looking forward to this cheapening as a means of recompense, and are determined, if possible, to prevent users taking advantage of it. What contracts there are, are mostly short-dated, makers declining to book any length of delivery at existing rates. Foundry iron is the quickest medium. Forge is unsteady, but there is little excess production. Hematite makers are sending big tonnages into the armament works. East Coast products are fractionally lower on the week, but West Coast sorts are firmly held at 73s. to 73s. 6d. Scrap rules at exceptionally low rates, but users are only making purchases where special bargains are to be obtained. The steel output is decidedly smaller on the month. Though unemployment is still very low, the excessive heat that has been experienced has had a restricting effect on all classes of manufacture. Makers, however, find no difficulty in keeping pace with current requirements. But for the heavy contracts recently placed, and upon which work is proceeding, difficulty would be experienced in maintaining constant activity in certain branches. The principal cause of reaction is the marked decline in export business. With important customers like British India, the United States, and Canada, there is something approaching a slump. Small increases are shown in the requirements of Australia and New Zealand. The prosperity in armament work is undiminished. Further big contracts have been booked, including, it is stated, several thousand tons of armour for H.M. battleship Renown, now building at Govan. A fair inquiry is experienced for axles, springs, tyres, and steel tools. Sales of agricultural machinery and implements are satisfactory. Billets are dull.

ALUMINIUM TUBES, SHEETS, WIRES, BAR, STRIP, AND RODS.—The British Aluminium Company, Limited, of 109, Queen Victoria-street, E.C., have issued a wall-sheet giving sections, thicknesses, weights, and areas of their productions, accompanied, in some instances, by comparison of similar weights of brass, copper, and steel. In regard to wire, the current it will carry, and the resistance per 1000 yards and per mile, are stated.

BRITISH RAIL EXPORTS.—The exports of rails from the United Kingdom in June were not so good as in June, 1913; but they were still considerable, coming out at 39,700 tons, as compared with 52,073 tons in June, last year, and 22,743 tons in June, 1912. Construction has slackened somewhat in Argentina, which only imported 18,832 tons of rails to June 30, this year, as compared with 26,451 tons and 22,997 tons. We sent 2881 tons of rails to Russia to June 30, this year, as compared with 25 tons and 36 tons respectively. The colonial demand has been as follows in the first half of the last three years:—

Colonial Group.	1914. tons.	1913. tons.	1912. tons.
British South Africa ..	40,416	33,984	21,267
British India	88,352	73,133	56,747
Australia	74,035	63,873	52,405
New Zealand	13,385	22,850	10,906
Canada	120	297	274

It is encouraging to find that construction is proceeding with some vigour in South Africa, and it may be reasonably expected that the demand for locomotives will improve in that quarter. The course of affairs in India leaves little to be desired; the growth of traffic has decidedly stimulated Indian railway development and improvement. There were apprehensions a few years ago that we should lose our Antipodean rail market, in consequence of the growth of American competition; but this development does not appear to be affecting our exports to Australia for the time being.

NOTES FROM CLEVELAND AND THE NORTHERN COUNTIES.

MIDDLESBROUGH, Wednesday.

The Cleveland Iron Trade.—Though there has been a little set-back in the demand for iron during the week, the current quotation for Cleveland g.m.b. is in advance of that prevailing seven days ago. Active purchasing is, however, not the rule, buyers being in no way keen to place orders at the prices prevailing. Sellers keep steadily to the quotation of 51s. 6d. as a general rule, but the fact that some makers are very desirous to enter new orders on their rapidly-depleting delivery list is not forgotten by buyers, who are only taking what is needed to cover immediate and pressing wants. Shipments, too, are less buoyant, Connal's stocks having increased to approximately 80,000 tons. There is not likely to be any greatly renewed activity until after the holidays, when briskness in the Continental demand is hoped for. The quotation for Cleveland No. 3 g.m.b. is 51s. 6d. prompt delivery, at which price business is done, whilst warrants are 51s. 4d. cash buyers, with sellers asking 2d. more. No. 1 is 54s.; foundry, No. 4 quality, 51s. 3d.; No. 4 forge, 50s. 6d. to 50s. 9d.; mottled and white, 50s. 3d.—all for prompt delivery. There is a fair inquiry for hematite. East Coast mixed numbers change hands at 59s., with No. 1 sixpence more, either for prompt or forward delivery. Best Rubio ore, 50 per cent. quality, is at 17s., ex-ship Tees. Blast-furnace coke, medium quality, 17s. 6d. delivered at furnaces, but buyers are not keen.

Stocks and Shipments.—The stock of Cleveland pig-iron in the public warrant stores now stands at 79,747 tons—all of which is No. 3 quality. Since the beginning of the month the stock has been increased by 1458 tons. Shipments of pig-iron from the Tees are on a moderate scale. To date this month they average 2595 tons per working day, the total despatches being returned at 33,738 tons, 30,968 tons of which have gone from Middlesbrough and 2770 tons from Skinningrove. To the same date last month the loadings were given at 29,392 tons, or a daily average of 2260 tons, and for the corresponding part of July a year ago the clearances reached 44,762 tons, or an average of 3443 tons per working day.

Manufactured Iron and Steel.—In the manufactured iron and steel industries there is very little new to report. New orders are scarce, and works are only kept busy on contracts made some months ago. Principal market quotations stand:—Common iron bars, 7*l.*; best bars, 7*l.* 7s. 6d.; best best bars, 7*l.* 15s.; packing iron, 5*l.* 5s.; iron ship-plates, 6*l.* 15s.; iron ship-angles, 7*l.*; iron ship-rivets, 7*l.* 5s.; iron girder plates, 7*l.* 5s.; steel bars (basic), 6*l.* 5s.; steel bars (Siemens), 6*l.* 5s.; steel ship-plates, 6*l.* 5s.; steel ship-angles, 5*l.* 15s.; steel boiler-plates, 7*l.*; steel joists, 6*l.* 12s. 6d.; steel strip, 6*l.* 5s.; steel hoops, 6*l.* 10s.—all less the customary 2½ per cent. discount; cast-iron columns, 7*l.* 7s. 6d.; cast-iron railway chairs, 4*l.* 5s.; light iron rails, 7*l.*; heavy steel rails, 5*l.* 15s. to 5*l.* 17s. 6d.; steel railway sleepers, 7*l.* 5s.—all net at works; galvanised corrugated sheets, No. 24 gauge, in bundles, 11*l.* 5s. f.o.b.—less 4 per cent.

Cleveland Miners' Wages.—To consider the question of wages to be paid to the miners during the ensuing three months, a meeting was held at Middlesbrough this week, between representatives of the Cleveland Ironstone Mine-owners, and the Cleveland Miners' representatives. Mr. A. F. Pease, who presided, said that the mine-owners sought for a reduction in wages of 1.20 per cent. The meeting was adjourned until the 27th, so that the matter could be placed before the miners.

CANADIAN PRECIOUS METALS.—Canada does not produce very much gold, but it is unmistakably rich in silver. In the first three months of this year the output of silver was 6,519,860 oz, valued at 3,549,566 dols. The production of gold was 61,032 oz., valued at 1,202,502 dols.

THE WORLD'S IRON ORE.—The output of iron ore in the principal countries of the world in 1911 was 87,836,000 tons. This total was made up as follows:—United States, 43,877,000 tons; Germany (including the Luxembourg), 29,399,000 tons; France, 16,372,000 tons; United Kingdom, 15,519,000 tons; Spain, 8,633,000 tons; Russia (excluding Finland), 6,882,000 tons; Sweden, 6,055,000 tons; Austria and Hungary, 4,640,000 tons; Canada, 188,000 tons; and Belgium, 148,000 tons. In 1912 the United States produced 55,150,000 tons; Germany, 32,190,000 tons; France, 18,744,000 tons; and the United Kingdom, 13,790,000 tons.

THE MIDLAND COAL-FIELD.—The Yorkshire and East Midland coalfield has exhibited of late great activity and expansion. The division comprises the East and West Ridings of Yorkshire and the counties of Lincoln, Nottingham, and Derby, except that part of Derbyshire which lies south of the Trent. It embraces the whole of the coalfields of Yorkshire, Nottinghamshire, and Derbyshire. The output of coal last year was 73,499,559 tons, showing an increase of 8,069,904 tons as compared with 1912. Of the whole quantity mined in the division, Yorkshire produced 60 per cent., Derbyshire 23½ per cent., and Nottinghamshire 16½ per cent. The proportion of coal produced last year by coal-cutting machines was 7,599,836 tons, as compared with 8,187,301 tons in 1912. Developments are still proceeding in the neighbourhood of Doncaster, and at no fewer than seven new collieries has sinking been started. In Nottinghamshire the hard-coal seam has been reached at the Rufford sinkings, and the Welbeck sinkings are making good progress. Eight miles south of Doncaster, a large venture, financed by German capital, has secured a mineral area of 20,000 acres and has started operations.

NOTES FROM THE SOUTH-WEST.

Cardiff.—The steam-coal trade has shown little change. Best Admiralties have exhibited strength, but most other descriptions have been the turn easier. The strike of marine engineers has hampered loading operations to a slight extent. The best Admiralty large has been quoted at 20s. 6d. to 22s.; best secondary qualities have made 18s. 6d. to 19s. 6d.; other secondary descriptions have brought 17s. 3d. to 17s. 9d. per ton; best bunker smalls have made 10s. 6d. to 10s. 9d.; and cargo smalls have realised 7s. 6d. to 8s. 3d. per ton. Best household coal has been quoted at 19s. to 20s.; good household qualities at 17s. to 18s.; No. 3 Rhondda large at 17s. 6d. to 17s. 9d.; and smalls at 12s. to 12s. 6d. per ton. No. 2 Rhondda large has made 12s. to 13s.; and No. 2 smalls have brought 8s. to 8s. 6d. per ton. Special foundry coke has realised 25s. to 27s.; good foundry coke, 20s. to 23s.; and furnace coke, 17s. to 19s. per ton. As regards iron ore, Rubio has made 16s. to 16s. 6d. per ton upon a basis of 50 per cent. of iron, and charges, including freight, insurance, &c., to Cardiff or Newport.

South Wales Coal.—In the South Wales division there were last year 609 mines at work, as compared with 622 in 1912. The total of 609 was made up as follows:—Breconshire, 25; Carmarthenshire, 65; Glamorgan, 392; Monmouthshire, 120; Pembrokeshire, 6; and Radnorshire, 1. The number of persons employed last year was 233,134, as compared with 225,535 in 1912. Of the 233,134 employed in 1913, the number working below ground was 198,123, and the number working above ground, 35,011. The output of coal in the area in 1913 was 56,830,072 tons, valued at 33,744,202*l.* The corresponding production in 1912 was 50,116,264 tons, valued at 27,891,043*l.* Of coal classified as anthracite the output last year was 4,833,159 tons, showing an increase of 480,149 tons. The output last year was 287 tons per person employed below ground, and 244 tons per person employed above and below ground. Of the total output, 242,978 tons were cut by electricity, and 396,741 tons by compressed air, coal-cutting machines being used in forty-one mines.

Minimising Fog Dangers.—The results of experiments conducted on the Canadian Northern Railway liner Royal George with a wireless direction-finder, were made known on a recent arrival of the vessel at Avonmouth. It is claimed for the invention that by its use, in the thickest of weather, and without the aid of compass or sextant, a ship's officers are enabled to determine her position when she is within a radius of 50 miles of a fixed wireless station or one on board a ship whose position is known. Further, should a vessel pick up on the apparatus the distress signals of another ship, she will be able to set her course towards their source.

Welsh Coal Shipments.—The shipments of coal, foreign and coastwise, from the five principal Welsh ports in the first six months of this year compared as follows with the corresponding shipments in the first six months of 1913:—Cardiff—foreign, 9,543,232 tons, as against 9,521,698 tons; coastwise, 1,407,250 tons, as against 1,401,130 tons. Newport—foreign, 2,272,617 tons, as against 2,349,787 tons; coastwise, 355,621 tons, as against 357,671 tons. Swansea—foreign, 1,605,242 tons, as against 1,709,549 tons; coastwise, 179,275 tons, as against 192,678 tons. Port Talbot—foreign, 778,553 tons, as against 981,197 tons; coastwise, 57,684 tons, as against 69,173 tons. Llanelly—foreign, 132,911 tons, as against 110,702 tons; coastwise, 40,843 tons, as against 29,407 tons. The aggregate shipments, foreign and coastwise, for the first half of this year were accordingly 16,373,228 tons, as compared with 16,722,992 tons in the first half of 1913.

Aberavon.—At the last meeting of the water-works committee of the Aberavon Town Council it was reported that the water in the reservoir was 17 ft. below the bye-wash, and that the committee was now procuring 111,000 gallons per day from the Ystradfellte supply of the Neath Rural District Council. The surveyor said the Neath District Council was prepared to supply a maximum of 220,000 gallons per day, and that the cost would be 500*l.* per annum. It was decided to ask the Neath District Council for a maximum supply. The surveyor was also instructed to report on the question of sinking a well on the moors.

An Engineering Appointment.—Mr. Alaric Hope has been appointed chief engineer of the Cardiff Railway, in succession to Mr. H. S. C. Ree, who has retired. Mr. Hope has for many years been chief assistant engineer to the Mersey Docks and Harbour Board. He will take up his new duties early in August. Mr. Hope is forty-two years of age, and he became associated with the Mersey Docks and Harbour Board in 1895.

SHIPPING IN THE SUEZ CANAL.—The increase in the size of vessels using the Suez Canal is an important feature. This tendency has been marked for some years, but the increase in 1913 was unusually large, the average tonnage rising from 3774 tons in 1912 to 3940 tons.

LOCOMOTIVE CONSTRUCTION IN BELGIUM.—The Administration of the Belgian State Railways has let contracts in three lots for sixty-eight locomotives. Fifteen Belgian firms took part in the competition. The Hainaut Metallurgical Works tendered for sixty eight-wheel coupled locomotives at 2732*l.* per engine. The St. Leonard's Company tendered for six engines at 2736*l.* per engine. The highest tender received was that of the Bousau Construction Workshop Company, which offered to supply four locomotives at 2758*l.* per engine. The John Cockerill Company obtained an order for four compound engines with four cylinders and six wheels coup'ed.

AGENTS FOR "ENGINEERING."

AUSTRALIA: Gordon and Gotch, Limited, Melbourne; Sydney; Brisbane; Perth. Turner and Henderson, Sydney, N.S.W. T. Willmett and Co., Townsville, North Queensland. W. C. Rigby, Adelaide, South Australia. Melville and Mullen, Melbourne, Victoria.
AUSTRIA-HUNGARY, Vienna: Lehmann and Wentzel, Kartnerstrasse.
BELGIUM: E. F. Satchell, 45, Avenue de Terneuzen, Brussels.
CANADA, Toronto, Ont.: Wm. Dawson and Sons, Manning Chambers. Montreal: Sells, Limited, 302 Shaugnessy Building, McGill-street.
EDINBURGH: John Menzies and Co., 12, Hanover-street.
FRANCE, Paris: Boyveau and Chevillet, 22, Rue de la Banque. For Subscriptions and Advertisements, Librairie B. Tignol, 53bis, Quai des Grands-Augustins, Paris. Also for Advertisements, Agence Havas, 8, Place de la Bourse.
GERMANY, Berlin: A. Asher and Co., 13, Unter den Linden. Leipzig: F. A. Brockhaus. Mulhouse: H. Stuckelberger.
GLASGOW: William Love.
INDIA, Calcutta: Thacker, Spink and Co. Bombay: Thacker and Co., Ltd.
ITALY: U. Hoepli, Milan, and any post-office.
LIVERPOOL: Mrs. Taylor, Landing Stages.
MANCHESTER: John Heywood, 143, Deansgate.
NEW ZEALAND: Gordon and Gotch Proprietary, Limited, Wellington, Auckland, and Christchurch.
NORWAY, Christiania: Cammermeyer's Boghandel, Carl Johans Gade, 41 and 43.
ROTTERDAM: H. A. Kramer and Son.
SOUTH AFRICA: Central News Agency, Limited, Head Office—Johannesburg; and Pretoria, Cape Town, Port Elizabeth, Bloemfontein, Durban, and their various branches and bookstalls throughout South Africa. Also Cape Town: Wm. Dawson and Sons, 31, Long-street.
TASMANIA: Gordon and Gotch Proprietary, Limited, Launceston; Hobart.
UNITED STATES, New York: W. H. Wiley, 432, Fourth Avenue. Chicago: H. V. Holmes, 957-958, Monadnock Block.

ADVERTISEMENT RATES.

The charge for advertisements is three shillings for the first four lines or under, and eightpence for each additional line. The line averages seven words. Payment must accompany all orders for single advertisements, otherwise their insertion cannot be guaranteed. Terms for displayed advertisements on the wrapper and on the inside pages may be obtained on application. The pages are 12 in. deep and 9 in. wide, divisible into four columns of 2¼ in. in width. Serial advertisements will be inserted with all practicable regularity, but absolute regularity cannot be guaranteed.

Advertisements intended for insertion in the current week's issue must be delivered not later than 5 p.m. on Thursday. In consequence of the necessity for going to press early with a portion of the edition, alterations for standing advertisements should be received not later than 1 p.m. on Tuesday in each week.

SUBSCRIPTIONS, HOME AND FOREIGN.

"ENGINEERING" can be supplied direct from the Publisher post free, for twelve months, at the following rates, payable in advance:—

For the United Kingdom	£1	9	2
For Canada—			
Thin paper copies	£1	11	6 ($7.65)
Thick ,, ...	£1	16	0 ($8.75)
For all other places abroad—			
Thin paper copies	£1	16	0
Thick ,, ...	£2	0	6

When foreign subscriptions are sent by Post-Office orders, advice should be sent to the Publisher.

Foreign and Colonial subscribers receiving incomplete copies through newsagents are requested to communicate the fact to the Publisher, together with the agent's name and address.

All accounts are payable to "ENGINEERING," LIMITED. Cheques should be crossed "Union of London and Smith's Bank, Limited, Charing Cross Branch." Post-Office Orders should be made payable at Bedford-street, Strand, W.C.

Offices for Publication and Advertisements, 35 and 36, Bedford-street, Strand, London, W.C.

We desire to call the attention of our readers to the fact that the above is our SOLE ADDRESS, and that no connection exists between this Journal and any other publications bearing somewhat similar titles.

TELEGRAPHIC ADDRESS } "ENGINEERING," WESTRAND, LONDON.

TELEPHONE NUMBERS—3663 and 8598 GERRARD.

READING-CASES.—Reading-cases which will hold twenty-six numbers of "ENGINEERING" may be had of the Publisher or of any newsagent. Price 6s. each.

ENGINEERING.

FRIDAY, JULY 17, 1914.

INDUSTRIAL PROFITS AND EXPERIMENTAL RESEARCH.

THERE can be no question about the decrease in the volume of trade in practically every industry. Lloyd's Return shows a diminution of 14 per cent. in the tonnage of the merchant ships in course of construction now as compared with a year ago, and, as there has been a great falling-off recently in the orders placed, the work in hand is in a much more advanced state than was the case at the former date, so that the tonnage, from the standpoint of employment still available, is considerably less than the percentage of the decrease indicates. Moreover, freights are low, and shipowners are indisposed to place orders unless under the most advantageous conditions. Many of the iron works are closing down part of their plant, as they experience great difficulty in keeping their order-books sufficiently full to justify reliance on the future. The Board of Trade Returns tell the same story, for the exports each month show a great decrease when comparison is made with the corresponding months of last year, the decrease for June being 6.9 per cent. In the textile industry, again, there is a prospect of short time being resorted to in order that the plant may be run in full working order, since the closing down of part of the producing machinery involves a diminution in the efficiency of the power plant. The future is therefore, on the face of it, somewhat disheartening, particularly as in no period of decline of activity has there been such keen cutting of prices. This is due in large measure to the fact that foreign countries are able to-day not only to meet a larger proportion of their own requirements, but are themselves entering into markets which hitherto have been regarded as exclusively the field of British enterprise. Indeed, in some cases Continental firms are underbidding British producers even in this country.

Such a condition is not altogether without some advantage, because it carries with it a lesson which ought to be enforced on every available occasion, and that lesson was very happily expressed by Sir William Beardmore on the occasion of the launch of the light armoured cruiser Inconstant some days ago. He stated that "the nation which does not continuously search for improvements must fall behind in the struggle for supremacy." In this matter it is not alone the capitalist who requires to assimilate the teaching of the experience of decadent trade. The workmen, and the leaders of the workmen's unions, must analyse the situation, because on the lessons which can be gathered from it depend in no small measure the encouragement to evolve improvement, as well as to adopt better methods and appliances. Usually, when trade is brisk, when orders arrive in satisfactory volume, and when it is possible to distribute over a wide area of production establishment and other recurring charges, the main idea is to meet demands for delivery—to ensure the maximum turnover in any given time. Volume is then the main idea in securing a reasonable return. But volume itself requires a large body of workers, and, unfortunately, the crude principle of supply and demand dominates the question of the remuneration of labour, and, through this, the cost of production and the amount of profit derivable from a given contract. Although it is admittedly in accordance with the tendencies of uncultured human nature, it is, nevertheless, to be deplored that a certain class of workmen will only put in a sufficient time at work to earn enough for their immediate needs. The trouble which the employers have experienced, not only in meeting contractual dates, but in achieving a satisfactory degree of efficiency from power plant and other producing mechanism, arises from the reduced number of hours which such mechanical appliances are in operation during each week. It follows, therefore, that the employers are not encouraged to improve their mechanical methods, since every improvement made will involve increased capital expenditure, and, therefore, a greater call for return on capital, while the men cannot be relied upon to utilise the plant to its highest producing capacity. At no time is this lesson more important than at present, when every effort must be put forth in order, as Sir William Beardmore pointed out, to obviate Britain falling behind in the struggle for supremacy.

In periods of great industrial activity there is little time and less mental effort available for the development of new ideas and the prosecution of experimental research. It is consequently well, in the interests of applied science, that we should have some relaxation from that intensity of work which falls not only upon the designer, but on the manufacturing managers of our great industrial concerns. The field is wide, and the need great, for effort in such directions. Sir William Beardmore, however, with that directness of attack which is characteristic of him, not only in his manufacturing methods, but in his few public utterances, put his finger on the difficulty in connection with this original research. "Experiments," as he pointed out, "cost much money, and yet it is of vital importance that experimental work should be encouraged, and unless a reasonable profit is made on all work there is less financial surplus to make such experiments, so that, apart altogether from the need to remunerate labour, and to give a return on the capital invested on plant which must be maintained in the highest efficiency at whatever cost, each contract should yield a sum for making progress." On this, indeed, depends our manufacturing supremacy. The question arises whether during the past great boom in trade sufficient profit was made to enable experimental work to be continued during the succeeding relaxation in output. Those firms who have not been making a profit, or who have been foolishly distributing their profits to the last pound, must experience a great disadvantage even immediately, and this must become more intense as the keenness of competition develops during depression in trade.

It is not without interest to glance briefly at the directions in which improvements must be effected, not only in production, but in methods of manufacture. Sir William was able to point with a large degree of satisfaction to the advances signalised in the design of the light armoured cruiser Inconstant, which his firm have just launched; and the First Sea Lord, Prince Louis of Battenberg, who was present at the launch along with his daughter, who christened the ship, pointed to the Beardmore Works as a notable example of continuous progress due to experiment and enterprise. Sir William pointed out, for instance, that the guns with which the vessel is fitted have five times the muzzle energy of those of the same size and weight available twenty years ago, while the improvement in projectiles gives them a still greater penetrative power. The armour, again, although the weight per square foot is only about one quarter, is of greater resisting power than that of twenty years ago. From each ton of machinery it is possible to get four times the horse-power for driving the ship as compared with fifteen years ago. Again, in respect to the structure of the ship and the armour, the improvements made are of still greater moment. The hull itself is of high-tensile steel, and the armour, made of steel of special constituents, and treated afterwards in processes recently evolved, is the result of a great amount of chemical and mechanical experiment made at the Parkhead Works and elsewhere. But for this experimental work in metallurgy, chemistry, and mechanical engineering, such vessels as the Inconstant could not have been built to-day.

One hears a great deal about the price paid for armour, but when one reflects on the enormous expenditure incurred in evolving new compositions and processes of heat and other treatment, the public must feel that the money is well spent. At the present moment the naval officer shows great anxiety regarding the protection of battleships. Mr. T. G. Owens' paper at the Institution of Naval Architects in April last, Sir John Biles's paper at Newcastle last week, and Sir Percy Scott's letters in *The Times*, all reflect this feeling of anxiety. Into the general controversy as to the part to be played relatively by the surface and submerged craft we do not propose again to enter, but there is undoubtedly a great consensus of opinion in favour of the battleship as our mainstay, because, as Lord Charles Beresford has pointed out, the submarine is essentially a weapon of defence, and British naval tactics must be offen-

sive. Consequently the surface vessel, and particularly the battleship, is of vital consequence to our naval supremacy. At the same time the battleship must be protected from the torpedo, the weapon of the submarine-boat. Whether this can be best done by placing armour on the outer surface of the ship below the water-line, or by constructing a series of internal armoured bulkheads, longitudinal and horizontal, as advocated by Mr. Owens, the fact remains that armour of effective resisting power, and yet of light weight, must be evolved, preferably of the "elastic" type. That being so, it is important that the armour-plate makers in this country, who have ever been to the forefront in the evolution of improvements, should be encouraged if our battleships are to be able to resist attack by the submarine-boat's torpedo.

It is, however, not alone in respect to war material that research should be made. In peace productions there is a wide field for advance. We are glad that in respect of metallurgy a new wave of enthusiasm has swept over the country as reflected by the papers at the technical institutions, and it is gratifying to know that even in establishments devoted to the building of tramp-steamers there is a fuller recognition of the importance of laboratory work in connection with iron and steel castings, while in other directions the composition of alloys is now being attacked with some degree of knowledge in chemistry and metallurgy. Indeed, the structure of metals is now accepted as a matter of primary importance. Again, in the field of thermodynamics the effect of superheating is being closely considered, and by experiment and careful observation in service improvements are being effected not only in the superheater itself, but in the condenser, in order to reduce the volume of saline in the feed-water. The system will certainly be more widely applied, its economy being now fully recognised. Another field in which experience is becoming more widely garnered has reference to the application of gear between the high-speed turbine and the slow-running propeller, and here again great advantage must accrue. On the care and capacity of the sea-going engineer, indeed, much more depends than is sometimes realised, and the more the steamship-owner encourages in his own staff observation and careful analysis of results, the greater will be the economy in service and the more valuable the experience utilisable in the design of ships and their machinery. Few engineers, for instance, realise how great is the waste that any steam leakage involves, owing to the steam required for the make-up water. Many other similar instances will occur to the reader in which the leisure which is certain to result from decreased activity in trade may be utilised to introduce improvements and to effect changes in methods of manufacture, so that in the future competition can be met not only by superiority in design, with a view to higher efficiency in service, but by higher economy in the workshop processes. We admit that the "fly in the ointment" is the working man and his organiser; but, even with this depressing disadvantage, the scientist must move forward, and, as far as is possible, carry the working man with him.

CATALONIAN TEXTILE INVENTIONS.

IT is a curious coincidence that just now when the interest of the textile industry—particularly the spinning branch—has been aroused by information relative to a new method of drafting cotton roving emanating from Catalonia, an essay on the Bergadana spinning-machine, one of the earliest types, should be published. The Catalonians have been recognised as extremely progressive in the advancement of the textile industry, and quite a number of important textile inventions have been evolved in the district around Barcelona. The essay* referred to deals with the history, construction, and operation of the Bergadana or Maxerina spinning-machine, which was really an improvement on Hargreaves' spinning-jenny. Hargreaves' machine, invented in 1764, was the first attempt to draft and spin a number of threads at one and the same time. The machine, although manually operated, was semi-automatic in its action, and certainly advanced the production of cotton-yarn very considerably. Essentially it consisted of a framework supporting a large driving-wheel turned by hand, which operated a tin roller, which, in turn, drove a series of upright spindles through bandings passing round the tin roller and the spindle wharves. Running along the top of the framework, in special grooves, was a wheeled carriage, provided with cross-bars placed one above the other and having grooves parallel to the frame sides. The cotton-roving was carried on bobbins placed on creel-pegs about the centre of the framework. This roving was drawn from the bobbins through the parallel grooves, and then practically in a straight horizontal line to the spindles. The grooved cross-bars were operated to trap the roving at certain times and to prevent delivery. The operation of the machine was simple. After the rovings had been drawn

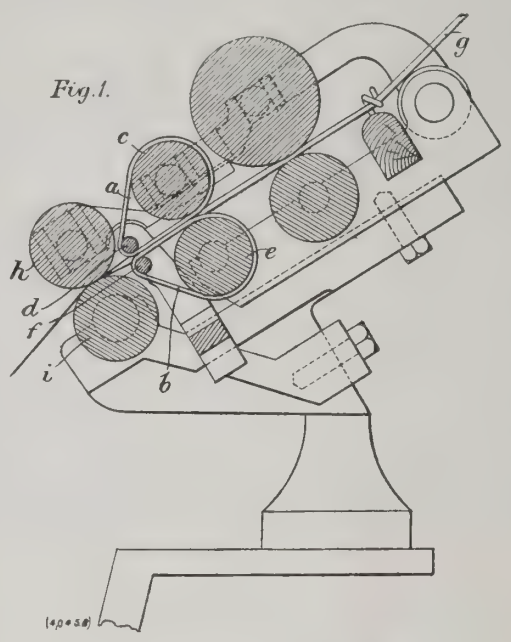

Fig. 1.

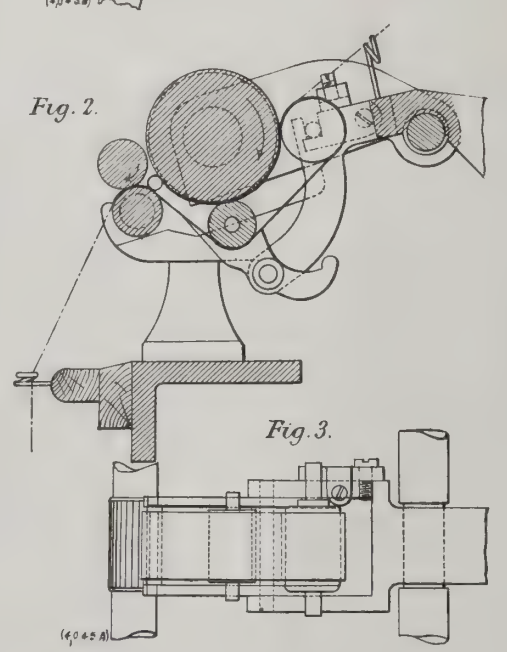

Fig. 2.

Fig. 3.

into position and attached to the spindles, the carriage was moved out by hand away from the spindles in a very similar manner to the way a carriage of a self-acting mule operates to-day. When a certain position was reached the cross-bars were closed, and the roving between the cross-bars and spindles was thus held. The handle and driving-wheel were then turned to rotate the spindles, and at the same time the carriage was moved outwards again, so that a simultaneous draft, or attenuation, and twist were imparted to give the desired fineness.

The Hargreaves frame had only a comparatively small number of spindles, about 40 or 50. The improved Bergadana machine had, however, some 130 spindles, and as the frame could easily be operated by a woman, the production per machine was considerably increased. Moreover, both warp and weft yarns could be produced equally well on the improved machine; but one drawback was that the cops produced could not go direct to the shuttle, but had to undergo a process for rewinding on a special winding-frame. Several variations between the original and improved machines are to be noted. In the latter, the drive of the tin roller was through gearing, whereby one revolution of the driving-wheel secured 315 revolutions of the spindles. The carriage, instead of being drawn out by hand, was dependent on the force of gravity of a single counterweight attached to either side of the carriage, so that even, regular movement was secured. The spindles were also mounted in a much better fashion, and the first attempt at really efficient lubrication was secured by employing a spindle-rail, with slots for the spindles and a strip of iron below, the slots being supplied with olive oil, the surplus dripping on to the iron strip. Two tiers of creel-pegs were necessary to support the roving bobbins. Means were also provided to tighten up the spindle-driving bands, such means being extremely simple, yet at the same time quite efficient. The faller-wire, which was arranged adjacent to the spindle, should not be overlooked. This wire, extending from side to side of the frame, was depressed when drafting and twisting was completed to guide the thread to the part of the spindle on which it had to be wound. In the Bergadana machine the method of operation was much simplified, and certainly reduced the work of the operative; in fact, the whole machine was evidently improved to secure greater production with less labour. Arkwright's spinning-frame, in which rollers and constantly-revolving spindles were used, saw the light in 1769. In this frame the drafting—or reduction of the number of fibres to the cross-section—was accomplished by pairs of rollers running at different rates of speed. The combination of the two methods—namely, the drafting by rollers and by a carriage carrying spindles moving out from the delivery of the material—was made by Samuel Crompton about the year 1779, the machine produced being termed a "mule," because of its hybrid nature. Recently what was stated to be a new method of drafting sliver and rovings in spinning-frames has been introduced in Catalonia. It must be understood that prior to the roving reaching the spinning-machines it passed through three speed-frames, a slubbing, intermediate and roving-frame, the whole object of these machines being to reduce the number of fibres to the cross-section of the material. The inventor of the new system, Don Casablanca, states that he can do away with two of these machines, and obtain a draft of 60 or 80 in the mule or ring-frame, and, at the same time, produce an even and regular yarn. His latest method of accomplishing this is illustrated in Fig. 1. It will be noted that endless bands *a* and *b* are employed, running round rollers *c* and *d* and *e* and *f*. These endless bands travel slowly, and the roving *g* passes between them. The front rollers *h* and *i* travel quickly, and the considerable drafting is occasioned by the creeping action of the fibres set up between the endless bands. The method is simple; but although it is stated to give excellent results, no full-length machine has yet been put to work. Naturally, the very big claims made for the Casablanca invention have evoked criticism, the most searching being that of Mr. Albert Meyer in *L'Avenir Textile*. Mr. Meyer's contention is that in 1903 he invented the system shown in Figs. 2 and 3, in which a single endless band was used. After continuous experiment, the invention was abandoned, chiefly because the cost of upkeep of leather bands was so considerable, 40,000 being required in an average-sized mill. Casablanca would require 80,000, and, moreover, he cannot get at his bands so easily as Meyer, the whole of the bottom rollers, 87, requiring to be taken out to replace one band. Meyer allowed for this by having a swing-piece which carried the rollers supporting the endless band. As the leather bands are the chief essential of the invention, it would appear that the system will be a costly one to maintain, and, moreover, great difficulty has been experienced in keeping the fibres in the centre of the bands.

* *Essay on the Catalan Cotton-Spinning Frame, known as the Bergadana or Maxerina Machine.* By Ramón N. Soler y Vilabella. Barcelona: J. Horta.

THE PORT OF CALCUTTA.

THE issue of the Report of the Calcutta Port Inquiry Commission is an event of no little significance to the trading community which it immediately concerns, while at the same time it is a matter of considerable interest to commercial and professional men generally, and especially to those in shipping circles. The congestion of trade at the premier port of the Indian Empire is bound to have a disturbing effect over a very wide area, apart from the consideration that during the past few

years it has become only too evident that the inability of the Port Authority to cope satisfactorily with an ever-increasing volume of commerce was seriously impeding the growth and development of the port, and undermining its prosperity. The situation has, in fact, become so intolerable and acute that immediate steps to deal with it are imperatively demanded.

Following upon some preliminary discussions with the Bengal Government, a conference of representative non-official gentlemen and railway expert authorities, summoned by the Bengal Chamber of Commerce, in August of last year, strongly advised the appointment of a Committee of Investigation, and the following seven gentlemen were ultimately invited to serve :—Sir Wm. Duke, K.C.I.E. (Chairman), Sir Henry Burt, K.C.I.E, the Hons. A. M. Monteath, J. C. Shorrock, and Raja Reshee Case Law, C.I.E., Mr. Anthony G. Lyster, and Mr. H. I. Howard, C.I.E., with Mr. R N. Reed as secretary. With the exception of Mr. Lyster, the President of the Institution of Civil Engineers, all the members had close association with the port of Calcutta and the Province of Bengal, and were intimately acquainted with local needs and conditions.

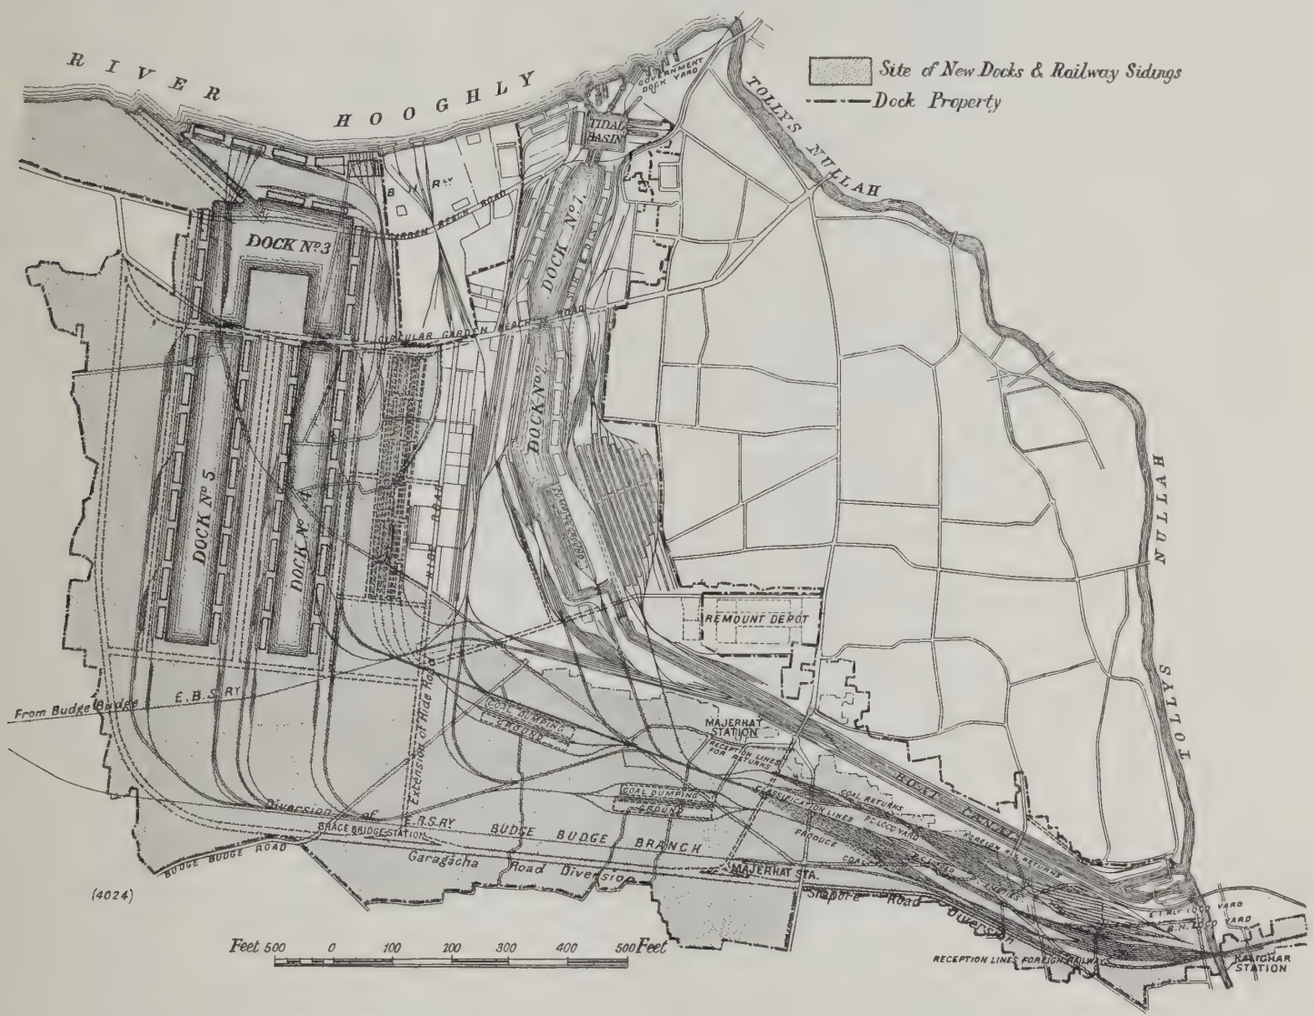
This is not by any means the first occasion in the recent history of the port on which a commission has been appointed to deal with the ever-recurring problem of trade expansion and the extension of shipping facilities. On the contrary, there have been many such committees — they have been an invariable resource in times of perplexity — and the only regrettable experience in connection with them is that they have not always proved an effective remedy for the evils they were called upon to palliate. This has not been so much the fault of the Committees as of the authorities, who, on receiving the Committee's recommendations, have pigeon-holed them as the most convenient form of disposal. As far back as 1846 a Commission recommended the construction of a dock for shipping at Kidderpore, but no action in this direction was taken for forty years, although many Committees sat and debated in the interval. Quite recently there were Committees in 1900-1 and in 1903, whose conclusions were merely of a negative character. A special "inquiry" of 1905 resulted in definite recommendations to the Government, which never materialised ; had they done so, the present investigation would not have been required. It remains to be seen whether the proposals now put forward are destined to meet with any more favourable fate than that of many of their predecessors.

The report is a lengthy one, comprising 75 pages of folio size. It would be impracticable to deal with all the points raised, and some of them are purely commercial and of merely local interest. The Committee covered a good deal of ground in the course of their investigations : organisation, finance, tolls and charges on goods and vessels, railway terminal payments, and the like. Apart from these, however, there is a technical side to the report, dealing with port improvement schemes, and this is the feature which will appeal most strongly to engineers. For reasons of space, if for no other, we must confine our observations to this section.

Sea-going shipping at Calcutta has hitherto been accommodated either at jetties in the River Hooghly or at the Kidderpore Docks. The river jetties consist of eight berths, with an aggregate frontage of 4150 lineal feet, furnished with sheds and warehouses for dealing with the import trade. A ninth berth, with a frontage of 585 lineal feet, is now nearing completion. The Kidderpore Docks, dating from 1892, contain seventeen berths for general produce and ten coaling-berths. There are also thirty-four transit and storage sheds, with a total floor area of over 1,000,000 sq. ft. The jetties have been particularly conspicuous for the degree of congestion prevailing along their frontage, and for the inadequacy of their facilities for the discharge of cargoes. Only four of them can accommodate vessels of 500 ft. length and over, and only three are so constructed as to render it possible to dredge with safety alongside to a depth of 25 ft. below lowest low water. The other five cannot be dredged to a depth greater than 13½ ft. below low water. Moreover, the constant dredging operations which are necessary, seriously interfere with the occupation of the berths by shipping, and they are largely rendered abortive by the slipping forward of silt from the banks within the jetty face.

At the docks the defects are in regard to insufficiency of accommodation and an unsatisfactory entrance arrangement. The quayage of Dock No. 1, which was formerly adequate for twelve vessels, now only suffices for eleven, and sometimes for ten. With the steady growth in the size of vessels (the average length of the ten largest vessels frequenting the port has increased by 100 ft. since 1880) the berthage will become more and more restricted, and the available accommodation correspondingly diminished. The defects of the entrances are even more serious and vital. There are two entrances—one a lock, 60 ft. wide, with a length of 400 ft. between gates, and the other, a simple entrance, 80 ft. wide, with a single pair of gates. Both are inadequate for the needs of modern shipping. The average beam of the ten largest ships using the port is 57 ft. 9½ in., which leaves an insignificant margin of width in the lock, while its length (despite the fact that by an ingenious contrivance of caissons it can be rendered serviceable to a maximum extent of 510 ft.), is quite insufficient for vessels even of moderate size, which are being built at the present day. The 80-ft. entrance lies at right angles to the stream, and can only be utilised at times of slack water, and then merely to a nominal extent, as, except on the few occasions on which the flood tide approaches the level of the water impounded within the dock, there is an excessive loss of water in passing ships in and out. There is at least one case on record where a vessel, too large for the 60-ft. entrance, was seriously delayed at the 80-ft. entrance. The sills of both entrances only give at lowest low water a depth of 19 ft. 6 in., although the docks themselves are suitable for vessels with a draught of 33 ft.

The shortcomings of the docks and jetties were recognised long ago, and the recommendations in



regard to dock extension put forward in 1906 by the then chief engineer to the Calcutta Port Trust (Mr. F. Palmer, C.I.E., subsequently Chief Engineer to the Port of London Authority, and widely known as the author of the "Proposals for the Improvement of the Port of London"), are practically identical with those which now receive the approval of the Commission. The scheme, as will be seen by the plan on page 93, comprises a new dock system on land which has already been acquired in the vicinity of Garden Reach, consisting of a turning basin or main dock, with a minimum dimension of 1000 ft., and two arms or branch docks, running approximately north and south, with widths of 600 ft. and 700 ft. respectively. The depth of the dock is fixed at 35 ft. The entrance is designed to allow continuous docking and undocking of vessels throughout the twenty-four hours. It is proposed that the lock shall have a length of 1200 ft., divisible into two sections of 700 ft. and 500 ft., by which it will be possible to pass either one or two vessels through the lock at a single operation, with a corresponding saving of time and of water. The width proposed is 90 ft.; in proportion to the length this seems somewhat meagre, especially in view of the tendency of naval architects to increase the ratio of beam to length. In Mr. Palmer's scheme the width was given as 100 ft., and this is certainly preferable. Widths of 100 ft. or over have been adopted at London, Liverpool, Newport, Avonmouth, and Bombay, and in the Panama, Kiel, and North Sea Canals. It cannot, therefore, be deemed an excessive allowance for future developments. The Commission's attitude on this point is the more strange, in that they fully recognise the necessity of avoiding the mistake made in the case of the existing entrances, where they expressly state that "expansion to meet the future growth of vessels has been restricted by cramped conditions." The docks are to be equipped with the usual sheds, and railway sidings and connections. No graving docks are shown on the plan accompanying the report, but it is understood that two are contemplated to be provided in the position shown in Mr. Palmer's plan of 1906—*i.e.*, at the end of the tongue between the arms.

The recommendations of the Commission involve an immediate expenditure approximating 3,000,000*l*. The Commission advocate the inception of the new dock, comprising its entrance and five internal berths, together with five riverside berths at Garden Reach, a distributing dépôt at Beliaghata for the delivery of imports from the docks, an enlarged junction yard for the reception and despatch of railway traffic, and the realignment of the Budge-Budge branch of the Eastern Bengal State Railway. The Commission are of opinion that it would be unwise to incur any large outlay in developing the present jetties, and their observations in this respect are confined to suggestions for relieving the congestion by more efficient service and attention to detail, until such time as the additional berths are available. They make several comments also upon the arrangements at the existing docks, more particularly in regard to the coal trade.

The navigable channel has not been overlooked, and there is a reference to the river approaches, the view being expressed :—(*a*) That the prosperity of the port will depend upon its capacity to receive the size and draught of vessels which navigate the Suez Canal, a condition involving a very considerable advance in the measure of improvement in the river approach channel ; (*b*) that it will be unwise to rest satisfied with a more or less empirical system of dredging as the sole means of river improvement ; and (*c*) that expert opinion will be necessary to solve satisfactorily the physical and economical problems which present themselves in connection with the improvement.

Apart from the immediate concerns of shipping and port accommodation, the Commission dealt with several questions of an engineering character, affecting the town and its external communications. They examined, for instance, the proposal to reconstruct the Howrah Bridge, and they endorse the demand for the construction of a new and much wider road bridge over the Hooghly, on the site of this existing bridge. They further recommend that a new railway bridge, providing more direct access to the docks, should be constructed within the next few years.

Such are, in brief, the principal conclusions of the Report. That, at a very early date, steps will have to be taken to improve, on very extended lines, the accommodation and facilities of the quays at the port of Calcutta, if it is to maintain unimpaired its prestige and commercial standing, is a proposition which no longer admits of any controversy, and with the representations of a highly competent body of professional and commercial men before them, the Government can hardly defer taking action. The report is, however, not merely the expression of the personal opinions of the signatories ; it reflects the views entertained by the majority of those interested in the port and its welfare. It devolves, therefore, upon the Port Trust to press the matter forward for immediate decision in order that they may continue to deserve the encomium passed upon them by the Commissioners, who affirm their conviction that the Trust "have developed their property, generally speaking, on sound lines, and with a zealous regard to the best interests of the Port."

DECREASED ACTIVITY IN SHIPBUILDING.

LLOYD'S Returns, just issued, show that, including merchant and war ships, there are in course of construction at the present time 567 vessels, aggregating 2,314,669 tons. This is 8.8 per cent. less than at the same date last year, notwithstanding that there is an increase in the number of warships now being built. It must be noted, moreover, that many of these warships have reached an advanced state of construction, and that, from the pure shipbuilding point of view, little remains to be done, many of them depending altogether on the completion of the guns, armour, and propelling machinery. Indeed, within the next three or four months there will be passed from the private shipbuilding works to the respective navies seven battleships, including the Turkish battleships Osman I. and Reshadieh, the British battle-cruiser Tiger, and the British battleships Benbow, Warspite, Queen Elizabeth, and the Emperor of India. Such a list, apart altogether from small war craft, will make a big difference in the total warship tonnage on hand. Thus, although Lloyd's list shows that 90 war vessels, of 592,545 tons, are building, these do not represent such a volume of work as the tonnage would seem to show. This applies in equal measure to the merchant shipping. Of merchant vessels there are 477, of 1,722,124 tons, in course of construction. When compared with a year ago, this total shows a decrease of 281,000 tons, and, when compared with fifteen months ago, when the total reached the maximum at any period in the history of shipbuilding, there is a decrease of over 331,000 tons. Thus the fall from the highest point is 16 per cent., from the figure of a year ago 14 per cent., and from the total of three months ago about 8.9 per cent. All the vessels are in a more advanced state than was the case three months ago, as, owing to the fewness of orders placed recently, there is less work to do in the shipbuilding yards of the United Kingdom. The figures of work now in progress, with those of a year ago, are given in the accompanying table :—

	July, 1914.		July, 1913.		Increase or Decrease.
	No.	Tons.	No.	Tons.	
					per cent.
Merchant ships ..	477	1,722,124	543	2,003,241	−14
H.M.S. (private yards)	60	306,030	57	273,149	+12
Foreign warships (private yards)	16	152,145	17	129,300	+17.6
	553	2,180,299	617	2,405,690	− 9.4
H.M.S. (dockyards) ..	14	134,370	14	132,190	+ 1.5
	567	2,314,669	631	2,537,880	− 8.8

As regards the condition in the various districts, there is, so far as merchant work is concerned, a decrease all round, excepting only Liverpool, where there is an improvement as compared with a year ago, but a slight falling-off as compared with three months ago. The largest decreases are in those districts where general traders are built. As compared with a year ago, the biggest falling-off is in Sunderland, where the reduction is 27 per cent., the number of vessels on hand now being 45, of 172,103 tons. Greenock comes next, with a reduction of 24 per cent., the number of vessels building being 49, of 229,710 tons. Then comes the Tees, with a falling-off equal to 23 per cent., there being in the yards now 42 vessels, of 82,504 tons. The Tyne on the other hand, has a decrease of only 8.7 per cent., the work there including 66 vessels, of 285,157 tons. At Hartlepool the reduction is only 3.5 per cent., the total vessels building numbering 19, and the tonnage 85,406 tons. Glasgow work, which earlier in the year had a slight rally, seems now to have dropped considerably, as the decrease since March last is equal to about 10 per cent., whereas when compared with a year ago the decrease is only 5.2 per cent. Belfast also seems to be suffering from the general depression, and here the 26 vessels, of 296,350 tons, in course of construction, mark a decrease of 18 per cent.

LITERATURE.

The Naval Annual, 1914. Edited by VISCOUNT HYTHE, D.C.L., A.I.N.A. London: William Clowes and Sons, 31, Haymarket, S.W. [Price 12s. 6d. net.]

THE "Naval Annual" appears this year about a month later than usual, owing to the fact that Lord Hythe has been devoting his time and energies to the furtherance of the federal solution of the great political question of the day. In his preface he states further that the duties of editorship have been in part undertaken by Mr. John Leyland and Captain C. N. Robinson. Lord Hythe has again to be congratulated on the maintenance of what is universally regarded as a standard work on current naval affairs. This is as it should be, because, apart altogether from the splendid traditions of the "Annual" established by Earl Brassey, and now maintained by his son, its publication is almost a necessary corollary of our position amongst the naval Powers of the world.

In the review of the progress of the British Navy, which forms Chapter I., Lord Hythe has had as collaborator Mr. Alexander Richardson, and the record is thoroughly comprehensive. It is again pointed out that two years is too short a period for the completion of the modern battleship, owing principally, as shown, to the resources of the armour-plate manufacturers being overtaxed, notwithstanding that there has been very considerable capital expenditure, not only to improve the processes of production, particularly hardening, but to augment the output. Within a few years the amount of armour required for each ship has increased from about 4500 to over 6000 tons, while the newer processes of treatment, whereby 10 to 15 per cent. has been added to the resistance to penetration by projectiles, involves longer time, more expert knowledge, and greater care. In the past two years one million sterling has been spent by each of two of the large firms, and to-day the annual output of the country is 65,000 tons. No other country in the world can equal this. Chief interest centres in the remarks made in regard to the policy of the Admiralty with reference to the overseas Dominions. The problem is one of great difficulty, because of the desire of the Dominions to have in their own possession, or within their territorial waters, ships sufficient to ensure their local defence; on the other hand, the claims of strategy require that ships should be in a position to attack the enemy if possible before he leaves his port. It must be confessed that there has been a considerable degree of vacillation on the part of the Admiralty ; irrespective of the wisdom of the policy decided upon at the Imperial Conference in London in 1909, there is some excuse for the Colonies insisting on its fulfilment. This policy required Australian, China, and East-Indian units for the Pacific, the idea being that the battle-cruiser New Zealand and a vessel of a similar type, as well as the battle-cruiser Australian, should be at the head of each of these respective units. So far as the two former ships are concerned, the arrangement has not been fulfilled, and there is some justification for the attitude taken up by Australia, who consider that, in addition to the vessels they have built, two cruisers of the "Town" class should be added from the Imperial Navy for Australian defence. As Lord Hythe points out, the whole problem of Imperial defence requires the earnest consideration of the statesmen of the Mother Country and of the overseas Dominions. Larger co-ordination of the efforts made is necessary, and it is to be hoped that the conference which will probably be held in 1915 will enable some agreement to be come to which will satisfy the desires of the Colonies, without interfering with the dominant needs of strategy. Lord Hythe

also makes the remark that "it is not reasonable that Canada should be defended at the expense of people who are being taxed out of their homes."

Mr. John Leyland is again responsible for the chapter reviewing the progress of all foreign navies. In this, as well as in the chapter on armaments by Captain Robinson, much interesting light is thrown on the policy of the various Powers regarding the gun-power of ships. First, as regards the calibre of the main armament, it is shown that several of the Powers have followed the British example by adopting the 15-in. gun; but it was only in the vessels of the 1913-14 programme that Germany adopted a gun of this size in preference to the 12-in. weapon. To-day Britain has ten battleships with 12-in. batteries, all complete; twelve ships with 13.5-in. batteries, of which ten are complete; and ten ships with 15-in. batteries, of which two have been launched. Germany, on the other hand, has four battleships with 11-in. batteries, all complete; thirteen with 12-in. batteries, nine being complete; while only two ships with 15-in. batteries have been laid down, and neither of these has been launched. The situation regarding battle-cruisers is equally illustrative of the progressive policy of our Admiralty. The United States in their battleships have adopted the 14-in. gun, and there is some talk of this year's ships being designed for eight 16-in. weapons. There is no indication of heavier guns than the 13.4-in. in the French Navy. Russia is fitting twelve 14-in. guns. The new ships for Italy are to have eight 15-in. guns, and Austria, like Germany, is adopting a similar armament. The 14-in. gun is being adhered to by the Japanese authorities in their latest ships. Of the secondary Powers, Spain in the new ships will probably fit eight 14-in. guns. Chili is adopting the 14-in. gun; Brazil, like the Argentine authorities, has adhered to the 12-in. gun, while it is probable that in the new Turkish ships the 13.5-in. or 14-in. gun will be adopted. The number of guns being fitted generally varies with the calibre; with the adoption of the 15-in. gun, it is found preferable to mount only eight; with 13.5-in. and 14-in. guns, ten, and in a few cases twelve guns are being mounted, as is the case with the 13.4-in. guns in the latest French ships. On the question of the number of guns in each turret, there seems still to be a difference of opinion; it is somewhat significant, as pointed out by Mr. Leyland, that in the new Italian and the new Austrian ships the triple-turret system is to be abandoned, the twin-turret being reverted to. But the French, in the ships now in progress, have four quadruple gun-turrets; the Americans and Russians are adopting triple gun-turrets. The American design differs in this respect, that, while in all the other ships with multiple-gun turrets, the guns are arranged with their axes at the same height above the water-line, the Americans have adopted the principle, now common with twin-gun turrets, of having the No. 2 and No. 3 turrets at a higher level respectively than the No. 1 and No. 4 turrets, so that they secure an end-on fire, either forward or aft, of six 14-in. guns. There is, however, a growing desire to have all the guns at the same height and to have a flush deck.

In regard to secondary armament, the tendency is to have as many of the guns as possible for bow-on fire, because, as pointed out by Captain Robinson, a 30-knot destroyer attacking a 20-knot battleship, will approach, when they are steaming in opposite directions, at a relative speed of 50 knots. Under such circumstances there is less time for ensuring accuracy, and the deficiency must be made up by rapidity and volume. On the other hand, where a destroyer is chasing a battleship with a view to bringing her torpedoes to bear, the relative speed is only 10 knots, so that the gunners in charge of the torpedo-boat-repelling armament have then longer time to ensure accuracy, and a smaller number of guns suffices. The secondary guns now being fitted are generally of about 6-in. bore. In destroyers the tendency is to fit two or three 4-in. guns, although Germany still has its faith pinned to the 15-pounder.

The Editor contributes, as usual, a very carefully prepared analysis of the comparative strength of the fleets. He points out that the balance of power is well preserved in Europe now, and Britain is holding her own in battleships. In the cruiser class we have a great superiority, but certainly not greater than is needed for the protection of our enormous oversea trade. As regards light cruisers, however, he does not think our position is satisfactory. The armament of the Arethusa and Calliope class—namely, two 6-in. and eight 4-in. guns—although respectable for the displacement, does not, in his view, seem powerful enough for dealing with a merchant-cruiser. Although the "Town" class of cruiser have a speed of three miles per hour less, he thinks their armament of eight 6-in. guns makes them valuable craft, and that more of them should have been built, instead of some of the light-armoured cruisers.

The engineering chapter is again contributed by Mr. Alexander Richardson, and is on the influence on speed of the weights added to ships (aerial, submarine, or surface) due to guns, armour, and other fighting requirements. It is pointed out that an effectively armoured barbette, with a pair of 14-in. guns, gun-mountings, structural supports, and the requisite ammunition, weighs approximately 1100 tons, while a triple-gun turret weighs 1520 tons, and a quadruple-gun turret 1920 tons. Obviously having the contention of Admiral Sir Reginald Custance in mind, the writer considers the effect of the reduction in the weight of broadside armour. If the thickness of the main belt on the latest ships were reduced so that it would resist 6-in. guns only, 1000 tons weight would be saved. The length of the ship could then be reduced by 10 ft. to 12 ft. Saving would also be effected in the structural weight of the hull, owing to the thinner armour carried. The same speed would be realised with 2000 shaft horse-power less, owing to the less displacement. Thus the gross reduction would be 1550 tons approximately. Were the reduction in the weight of armour utilised for increasing the speed, half of the 1000 tons would be available for the heavier machinery and half for the increased length of ship to accommodate the more powerful machinery; the final result would be an increase of $1\frac{1}{2}$ miles per hour to the speed. Another alternative for utilising the 1000 tons saved in armour would be the addition of a twin-gun turret, which could be fitted with very little difference in the size or speed of the ship. Were it desired to increase the number of turrets of the present-day ships from four to five—to increase the number of guns from eight to ten—the speed of the ship, other things being equal, would be reduced by $1\frac{1}{2}$ miles per hour. The same problem is discussed in connection with light cruisers and destroyers, the advantages of geared turbines, superheated steam, and other improvements being considered. As regards submarine-boats, interesting data are given as to the adoption of steam-turbines in substitution for Diesel engines, and the effect on size, power, and speed of fitting 12-pounder, 4-in., or 6-in. guns is reviewed. With four guns of 4-in. calibre, instead of the same number of 12-pounders, the weight of the armament with ammunition would be increased by 12 tons, but the displacement of the ship, in order to get the same speed, would be increased about 100 tons, while the adoption of 6-in. guns, involving, with their ammunition, a net increase of 78 tons, would require a gross addition to the displacement of 200 tons. The difficulty, however, is to get higher speeds in submarine-boats, as this involves a rapid increase in the weight of machinery. Consequently the problem of the future is one largely for the marine engineer. Loads on airships and aeroplanes are considered from the same standpoint.

The subject of wireless telegraphy in the Navy is dealt with by Commander C. F. Loring, R.N., now inspector of wireless telegraphy to the Post Office. The treatment is in part historical. On the Vernon alone there are now about twenty officers whose duties are solely connected with wireless telegraphy, as compared with three or four in 1904, while the number of trained operators in the Fleet in 1912 was over 1100. At the end of 1913 there were 435 warships and 30 stations equipped with wireless telegraphy in the Navy, as compared with 42 and 8 respectively at the end of 1900. In submarine boats communication can be maintained so long as the vessel remains on the surface, but when once totally submerged it appears impossible to establish any connection with the outside world. In airships communication is fairly satisfactory, though the ranges obtainable are not great in comparison with the radius of action of the airships. Signals can be sent from aeroplanes; but owing to the noise of the engine exhaust, the rush of air, and such causes as vibration, it has been impossible to instal apparatus for the satisfactory reception of signals by anyone in an aeroplane or sea-plane. Sound-proof helmets and other devices are being tried, and promise a reasonable degree of success. Wireless telephony has been under regular observation in the Navy since 1909, but, so far, has not attained a degree of reliability which would justify its adoption for fleet work, particularly in view of the success of wireless telegraphy. As regards surface ships, an admiral in European waters can receive instructions from his base, no matter where he is, from one or other of the high-powered wireless telegraph stations. He can inter-communicate directly with his base at ranges of 500 miles or more by making special arrangements, and he is always in direct touch with any of his ships at distances up to 500 miles, according to their size. Commander Loring refers to atmospherics (or X's) as the most serious difficulty experienced in wireless telegraphy. The special difficulty they give rise to is thus explained by him:—"A receiving aerial system can be designed to oscillate to one particular wave-length to the practical exclusion of all others, but an atmospheric is too often a purely local effect, and causes the aerial system to oscillate with its own period; consequently, no alteration of the local receiving tuning arrangements makes any difference—the circuits still oscillate to the local disturbances, and the desired signals of the distant station are blurred." He caused a record to be kept for a year of all such disturbances at one of the coast stations in the Channel, and he groups the disturbances under three heads: "moderate," meaning that the signals were unaffected at normal ranges; "strong," that they were difficult at normal ranges; "violent," that they were impossible at normal ranges. During the year there were 385 hours of violent disturbances, during which wireless communication at normal ranges was absolutely impossible. September was the worst month, 94 cases being recorded. In addition, there were 285 hours during the year when the signalling was difficult at normal ranges, and 222 hours when the disturbances were moderate and the signals unaffected at normal ranges. His experience is that, in the north of Europe, atmospheric disturbances are usually most prevalent in July, August, and September.

There is a very informative chapter on the British and foreign aircraft, the work done by all nations being carefully reviewed. Great Britain, it is pointed out, still holds the lead in seaplanes, although the collection is somewhat heterogeneous. All nations agree that more powerful engines are required in seaplanes, and it may be accepted that machines with engines of 300 or 400 horse-power will be flying in the course of the next few months. Efforts are being made in all countries to reduce the vulnerability of airships by subdividing them into compartments, and by fitting light fabric screens inside, with a view to these being sucked into a hole, if made by a projectile or otherwise, and thereby closing it. It is pointed out that the aeroplane is in a more advanced state of development than the airship, but the possibilities of the latter are now beginning to be realised outside Germany, and all the important nations are taking up the work. The writer of a chapter to which no name is attached thinks that if aircraft could be fitted with water propellers, and be designed so as to be able to alight on the water and to use the propellers when there was a high wind, a great step forward would be made.

There is a very suggestive chapter by a naval officer on naval literature, advocating that capable writers should be encouraged by the Admiralty to prepare theses on various phases of naval warfare, so that students of strategy might have placed at their disposal, from the great mass of history, accurate lessons from the war experience of the past. Mr. John Leyland gives a very interesting description of the German dockyards, all of which he has visited under conditions conducive to the acquisition of a full conception of their equipment. Admiral Sir John Slade has a chapter on the right of capture in maritime war, and Captain Robinson deals with the operation of the Greek and Turkish fleets during the Balkan war. These special chapters, combined with the usual lists of ships (surface, submarine, and aerial), plans of all the latest ships, Captain Robinson's very complete and well-illustrated description of the new developments in armour and ordnance of all kinds, along with a table of ballistics of the guns of all nations and makers, make up

a volume which is, at least, equal to any of the former issues of the "Naval Annual," and higher praise, we think, cannot be given.

THE GERMAN ASSOCIATION OF GAS AND WATER ENGINEERS AT MUNICH.

UNDER the presidency of Dr. Reese, Royal Government Surveyor, of Dortmund, the fifty-fifth annual meeting of the German Association of Gas and Water Engineers was held at Munich, the capital of Bavaria, from July 1 to 4. The number of names registered on the preliminary attendance list was 1334; the final list comprised about 1500 names, of which about three hundred were those of ladies.

With due observance of the usual custom, a social gathering to inaugurate the proceedings took place on Tuesday evening, June 30, when the large hall of the Hackerbräukeller, in the Theresienhöhe, was crowded. The reception was given by the Municipality of Munich, whose welcome was expressed by one of the members of the Town Council, by Herr Pschorr, President of the Munich Gas Exhibition, and by Herr Lempelius, its leading spirit, and Director of the German Commercial Gas Association for popularising the uses of gas. Members of the Committee of the German Association were present in large numbers, and guests from abroad were represented by M. Boutan, President de la Société Technique de l'Industrie du Gaz en France; M. de la Paulle, of Brussels, Belgian Association of Gas Engineers; Mr. George Weinberg, of St. Petersburg, Society of Russian Water and Sanitary Engineers; Dr. A. H. Elliott, American Gas Institute; de Heer J. van Rossum du Chattel, Dutch Association of Gas Engineers; Mr. O. Pihl, President of the Norwegian Association of Gas Engineers; Sig. Marcel de Jongh, Italian Society of Gas and Water Engineers; Mr. John Bond, Mr. W. E Price, and Mr. Walter T. Dunn, President, Honorary Secretary, and Secretary respectively of the Institution of Gas Engineers; and Bailie Thomas Paxton and Mr. W. M. Mason, the respective President and Secretary of the British Commercial Gas Association, representing Great Britain.

On the following morning, punctually at nine o'clock, the members were ready to commence the business of the meeting, held at the capacious Bayerischenhof, Promenadeplatz.

After a very cordial welcome to the delegates from abroad, the President, Dr. Reese opened the Congress by an address. This was followed by a paper by Herr Lempelius on "The Present State of the German Gas Industry, and the Munich Gas Exhibition of 1914." A paper on "Gas and Hygiene" was given by Professor Dr. M. von Gruber (Royal Privy Council, and of the Medical Council of the Municipality of Munich); "The Work of the German Gas Industry for the Good of the Community" was the title of a paper by Mr. E. Körting, of Berlin. The Report on the Question of the International Standardisation of Gas-Threads, by Sir William Lindley, of Frankfort-on-Maine, was down as the last item of the first day's session, but Sir William unfortunately was prevented from attending to read it himself.

The programme of the second session was as follows:—(1) "Prussian Water Board Regulations in Connection with Town Water Supply," by Herr Kreutz, Government Counsel and Life Member of the State Water Board, of Berlin; (2) "The Influence of Forests on Water Supply," by Herr Ernst Henle, of Munich; (3) "Removing Manganese from Water," by Professor Dr. Tillmans, of Frankfort-on-Maine; (4) "Removing Manganese from Artesian Well Water in the Elbe Valley, and the Dresden Plants in connection therewith," by Herr Otto Vollmar, of Dresden; (5) "Biological Results of Rapid Filtration at the Barmer Weir," by Professor Kolwitz, of Berlin; (6) "A Graphic Method of Measuring the Electric Drive of Pumps," by Herr M. Gaze, Chief Engineer of the Allgemeine-Elektrizitäts-Gesellschaft, of Berlin.

The programme, which was considered and discussed at some length at the third session, on Friday, July 3, consisted of:—(1) "Questions Relating to the Prices of Gas;" (2) "Communications on the Subject of Gas Heating," from Dr. Karl Bunte, the Secretary of the Association, who is in charge of its experimental and testing works and laboratory at Carlsruhe, a place doing most excellent and useful work. In view of the important results achieved, we would suggest to the British gas-engineering profession the great desirability of forming a similar institution in London. (3) "Report of work done during the past year by the following Commissions of the Association:—On gas meters, on standard threads, on water-works management, on education and experiments, on gas-works management, on light measurement, and on pipe questions." We hope at a later date to publish abstracts of some of these papers.

The annual report of the Council was presented, and consideration was given to the Simon Schiele donation and to arrangements for next year. The election of President, Council, Committees, and Commissions took place, Dr. Reese, of Dortmund, being elected for the third year in succession as President of the Association.

On Wednesday afternoon, the 1st inst., the Isaria Gas-Meter Works and the Dachauerstrasse Gas Works of the Municipality of Munich were visited by the members. At the latter was shown one of the latest examples of a Munich inclined chamber-oven installation. This system seems to bid fair to rival the well-known vertical-retort processes, and in places where extension of plant is under consideration it will doubtless receive due regard. Low labour costs, facility of operation, cleanliness, and general efficiency are notable characteristics.

The same evening the special incident of the meeting occurred—viz., the formal opening of the German Gas Exhibition. Its royal patron, His Majesty King Ludwig III., was to have performed the ceremony, but owing to the tragic assassination of the Archduke Francis Ferdinand (who was related to him) and his consort the Duchess of Honenberg at Sarajevo, on the previous Saturday, it was carried out by the Prime Minister, His Excellency Dr. Georg Graf von Herthing, who was accompanied by the other Ministers of State, and representatives of the naval and military services.

The members of the Association and all the visitors have nothing but praise to bestow on the President of the Exhibition, and on all those who have been responsible for its organisation and realisation. It is, indeed, excellent in every particular, but the critic from abroad must not forget that the promoters were specially fortunate in having at their disposal existing buildings which are so well adapted to their varied requirements. The buildings, which belong to the Municipality, are situated on the Theresienhöhe, and have indeed been designed and erected solely for exhibition purposes, and there is usually an exhibition in course of installation, or one being held, at all times of the year. Beautifully-laid-out gardens, open free to the public, surround the buildings, and there are cafés, with bands playing, and all the other usual enjoyable accompaniments of a Continental exposition.

The exhibits are divided into the following sections:—(1) Scientific and historical; (2) gas-works management; (3) manufacture of illuminating gas; (4) distribution, measurement, and installation; (5) gas-lighting for houses and streets; (6) capacity of a cubic metre of gas as regards light, heat, and power; (7) gas in the kitchen, the household, and the school; (8) bath and other water-heating; (9) warming of houses; (10) gas for industrial purposes; (11) gas-engines; (12) gas for airships; (13) the treatment and utilisation of by-products; (14) gas (other than coal-gas) as applied to various industries.

The Bavarian Aero Club will hold, in connection with the Exhibition, from August 14 to 17, a balloon display, in which the Royal Bavarian and the German Automobile Clubs will take part, showing auto-wagons, &c., for the conveyance of balloons.

That part of the grounds leading up to the entrance is flanked on either side by a number of tastefully-designed pilons, from the summits of which gas flares away Greek fashion. In the grounds are some good examples of outdoor gas-lighting, on the Graetzin system. Amongst the striking exhibits inside is a very fine and complete model of a gas works, made by Friedrich Schroder, of Munich, which cost about 1000*l*. It is shown in motion, electric motors being employed for driving it. Its destination at the conclusion of the Exhibition is to be the German Museum already referred to. Perhaps no better graphic representation of the weight of nickel placed in the prepayment gas-meters of Berlin during the past ten years could be imagined than that which was erected for the purpose in a prominent position in the Exhibition. It consisted of a magnification of a 10-pfennig piece, about 30 ft. in diameter and exactly 1 metre thick. There are also shown numerous models of gas plants; well-produced pictures and photographs of various works throughout the German Empire; samples of pipes, vertical retorts, and interior lighting most artistically arranged.

Exhibits by British firms seemed to be conspicuous by their absence, although in one case was noticed some of the instruments with which Messrs. Alexander Wright and Co., of Westminster, have won a world-wide reputation—namely, their new gravitometer, calorimeter, &c. The latter apparatus, of course, will now come into great demand as a result of the recent Parliamentary Bills promoted by the Gas Light and Coke Company, the Liverpool Gas Company, and other companies, whereby calorific power is to be taken as the test for gas, superseding the test for candle value.

Another interesting exhibit which claimed attention was that from the Association's testing laboratory and training college at Carlsruhe, for intending gas engineers and chemists, under the direction of Dr. Karl Bunte. This exhibit comprised replicas of the apparatus used in teaching, results of the experiments conducted under the supervision of Dr. Bunte, diagrams, &c. There were numerous other exhibits which might be written upon, but considerations of space prevent our noticing them.

The Association's annual dinner took place at the Bayerischer Hof, on Friday evening, July 3, the President, Dr. Reese, occupying the chair. The total number present was about seventeen hundred, but notwithstanding the immense number of the company the occasion passed off in a most enjoyable manner without the slightest hitch.

On the following day (Saturday) there were four non-technical excursions available. The German Association of Gas and Water Engineers have to deal with large numbers at their meetings and excursions, numbers with which the technical associations of Great Britain are unaccustomed, unless it be the British Association. The writer therefore cannot refrain from closing this report with a note of praise and admiration on account of the excellent way everything was arranged and conducted from beginning to finish. The representatives of Great Britain particularly, about 20 in number, were highly gratified at the warmth of their reception throughout the whole course of the week's proceedings.

INDUSTRIAL NOTES.

WE learn from the *Board of Trade Labour Gazette* that employment in June showed some decline on the previous month, but was still good generally. The pig-iron and iron and steel trades remained almost stationary, but employment in the engineering and shipbuilding trades slightly declined. In the tin-plate trade there was a decrease in the number of mills working. The coal-mining, furnishing, boot and shoe, and glass trades were not so well employed as in May, and there was some falling-off in the textile industries, especially in the case of woollen and lace manufacture. The building trades showed little change.

Compared with the high level of a year ago there was, on the whole, a decline, which was especially noticeable in the pig-iron, iron and steel, engineering, shipbuilding, woollen, and lace trades. There was, however, some improvement in the printing, boot and shoe, and brick trades, and a considerable increase in the number of tin-plate mills working.

Amongst those whose wages were reduced were 141,550 coal, iron, and shale mine workers in Scotland, and 34,250 iron and steel workers in the North of England, the Midlands, South Wales, and Scotland. The principal increase affected 4000 ironmoulders in Lancashire. The net result of all the changes reported was a decrease of 9600*l*. in the weekly wages of 190,000 workpeople.

The dispute in the building trades in London continued throughout the month, and is still in progress. The number of new disputes in June was 118, and the total number of workpeople involved in all disputes in progress was 82,752, as compared with 76,779 in the previous month and 122,623 in June, 1913. The estimated total aggregate duration of all disputes during the month was 1,072,900 working days, as compared with 1,040,900 in May, 1914, and 1,718,200 in June, 1913.

In connection with the strike last week at the Woolwich Arsenal, the Court appointed to inquire into the matter has been formed as follows:—Sir G. Askwith (chairman), Sir Clarendon Hyde, Colonel J. M. Denny (representing the Arsenal authorities), Mr. G. N. Barnes and Mr. J. R. Clynes (representing the employees). The Court commenced its sittings on Monday. The sittings will be in private, and a report will be made to the Secretary of State for War. The men all returned to work on Thursday, the 9th inst.

The Board of Guardians of West Ham last week went on strike as the result of the interference of the Local Government Board auditor with regard to payments for out-relief. The auditor recently requested the Board to meet him to discuss certain payments made, and on the 9th inst. the Board adopted a resolution declining to administer further out-relief unless allowed to do so at their discretion. The Local Government Board pointed out that the auditor was required by law to review the expenditure of the guardians on out-relief.

A "recognition" and anti "non-union" strike has developed at Liverpool, where the Mersey Docks and Harbour Board has refused the demand of the men in the warehouses and engineering departments for a conciliation board and the employment of only union labour. About 3000 men were called out. The bodies supporting the demand for recognition are the Transport Workers' Federation and the Engineering and Shipbuilding Trades' Federation. About 2000 men came out on Monday at Liverpool and Birkenhead. There have been threats of sympathetic strikes in London if the attempt is made to divert Mersey traffic to the Thames. The Board has issued a statement to the effect that it is determined to make every effort to preserve the liberty of labour and equal rights for

all. A large number of the older men have refused to strike. The prospects of loss of pensions and other privileges are acting as deterrents. The employees of the Board on the established list enjoy many advantages, including continuity of employment, superannuation allowance, liberal sick allowance, and, many of them, leave on full pay. At the time of going to press the strike had not assumed the formidable proportions at first promised.

At a meeting on the 9th inst. the men's representatives on the Coal Conciliation Board for the Federated Districts of England and North Wales agreed to submit to the Board a proposal for increasing the basis rate of miners' wages 50 per cent. The present rates are 50 to 65 per cent. above the 1888 basis. The Miners' Federation proposes to terminate existing agreements next year.

An interesting arrangement has been arrived at in connection with questions of demarcation at Messrs. Harland and Wolff's Works, Belfast. We quote from the United Society of Boiler-Makers and Iron and Steel Shipbuilders' report as follows:—The trades concerned shall give evidence before a neutral chairman appointed by the Board of Trade. The firm shall also give evidence, and thereafter the trades concerned, with the neutral chairman, shall endeavour to agree on a decision, *in the absence of the firm's representatives*. If the trades concerned fail to agree, then the neutral chairman shall give a decision.

At the Dowlais Collieries of Messrs. Guest, Keen, and Nettlefolds, Limited, about 4000 men struck work on Monday last as a protest against the employment of about 200 men not belonging to the Miners' Federation. On Wednesday only three men still remained outside, and work had been resumed.

Before the Committee which is inquiring into the Prevention of Railway Accidents, Mr. J. H. Thomas, M.P., on Tuesday last, asserted that many of the accidents were due to "speeding up" and to the payment of bonuses. Among other recommendations, he asked that the Board of Trade should have power to enforce the recommendations of their inspectors. It has often been pointed out that this could not well be done without making the Board of Trade responsible for the safety of the railways.

In an interim report of the Dominions Royal Commission, just issued, it is pointed out with regard to the white labour question in the Transvaal that if two Europeans replaced three natives at their present pay of 3s. 2d. per shift, and the Europeans received 10s., out of fifty-two producing mines twenty-six would cease to make a profit. If the white labourers received 12s. 6d., the rate of pay in Western Australia, where living is cheaper, thirty-five out of these fifty-two mines would cease to pay. It is stated that "it is clear that high remuneration divorced from certainty and other conditions essential to a contented and well-ordered life cannot be a panacea for industrial discontent." The opinion is recorded that the conditions would be better met by the employment of fewer white men, but of a superior class, so that they might be given more responsibility in regard to the native unskilled labour without fear of the power being abused.

We notice that in the Associated Blacksmiths and Iron-Workers' Society's monthly report for June that attention is drawn to a recent compensation case of some interest. A blacksmith employed by Messrs. Petrie and Co., Limited, Rochdale, received an injury in 1913 by which he lost the sight of his right eye. It was stated for the employers that the man's average wages before the accident of 36s. 10d. per week were still being paid, with 18s. 6d. per week compensation. The man had been offered his old or other employment, but had refused, and the firm asked for an order terminating or reducing the compensation. On the part of the man it was contended that he was unable to perform his former work. Four one-eyed blacksmiths were called, two of them having met with their injuries when over thirty years of age, and attested their ability to follow their employment without inconvenience. It was decided that the man was able to follow his former employment, and that the compensation must stop.

The United Pattern-Makers' Association report for June states that at the end of that month 394 members, or 4.5 per cent. of the membership, were on the vacant-books. The number was 65 above that in the previous month. The society has a total membership of 8628, of which 19 were on strike during June. Trade was reported as bad, dull, unquiet, &c., in quite a number of places. A wages movement at Bolton and Bury was settled during the month, the men accepting an offer of 1s. advance on the first pay in July and 1s. six months later, with an agreement for four years. At Keighley work was resumed on July 6 on terms rejected by ballot three weeks previously. The allied trades in the London district, whose five years' agreement expires in August, are preparing a demand for an 8s. per week advance. The movement is supported by the Amalgamated Society of Engineers, Steam-Engine Makers, Electrical Trade Unions, Brass-Finishers, and other societies. The United Pattern-Makers' Association is contemplating joining the movement under certain conditions.

In the quarterly report of the Cleveland Miners' Association, Mr. H. Dack, President of the Association, states that he is opposed to the policy of building up union funds with the idea of financing strikes to improve the workers' position. It had taken Cleveland eleven years after the Durham strike of 1892 to regain the same volume of trade as was being done just before the strike, and even to-day some of those buyers who formerly took Cleveland iron had not been won back.

The July report of the Steam-Engine Makers' Society states that the number of unemployed was only 153 in that month, or 0.9 per cent. of the membership, but compared with 108 in the previous month. There were 346 members on the sick fund, an increase of 70 on the previous month. The branch reports show that in most districts trade continues from fair to good, though in a few cases it is described as not so good, only moderate, or unsteady.

The building trades' dispute underwent some changes in the week. Preparations are being made in the provinces for the national lock-out, meetings being held daily with a view to making the necessary arrangements. The non-associated master builders, who are said to number about 300 firms, excluding jobbing builders, met in conference in London on Tuesday, with the result that a decision was arrived at that unless a settlement were reached in the interim, all firms represented at the meeting would close their works to union labour on August 1. It was also decided to appoint a committee to see whether the basis of membership of the London Master Builders' Association could be broadened, so as to bring in all classes of master builders in the London district. In the event of a national lock-out, about 6000 employers and a quarter of a million men will be affected.

There has of late been a great deal of unrest in Norwegian labour, and the men have more than once resorted to violent measures. The most recent examples of their reckless doings have occurred at the Nydalen Works. On July 8 more than 800 hands, practically the whole staff, left the factory with much shouting and disturbance after breakfast time instead of resuming work, and this they did without notice and in the absence of any dispute as to pay or hours. The female hands appear to have been the most disorderly. The demonstration was principally directed against a Swiss engineer. The trouble was at once reported to the Norwegian Employers' Union.

At the ordinary monthly meeting of the Council of the Leeds Chamber of Commerce, held on Tuesday, the 30th ult., the chairman, Mr. F. J. Kitson, moved the following resolution, with which we fully agree:—"That the Council of the Leeds Chamber of Commerce are of opinion that Consular appointments should, as far as possible, be confined to men of British nationality, who have a knowledge of at least two foreign languages, of which one shall be French, and have had special training in commercial subjects; that all appointments at the ports and other centres of industry should be salaried ones, and should provide, where necessary, for whole-time service, and that the degree of Bachelor of Commerce, conferred at the Leeds University, should be a qualification for a Consular appointment, but should be followed by a course of inspection of works in connection with some of the main industries of the country . . ." He and Mr. Bedford, one of the vice-presidents of the Chamber, he said, had gone very fully into the subject, and were strongly of opinion that Consular appointments should be given to British subjects, and that whenever possible the practice of giving such appointments to foreigners should be avoided. They thought also that these appointments should be made on merit, and not merely because a man happened to possess a title, which was, he believed, sometimes deemed sufficient qualification.

Mr. J. E. Bedford seconded the resolution. He urged that there should be a carefully followed method of selecting men to fill such positions as that of British Consul in foreign countries. In times gone by, he was afraid, these posts had been given to retired soldiers or to superannuated naval officers. Those no doubt were very estimable men, but, from a commercial standpoint, unless they had special knowledge or training for the work, they were scarcely suitable candidates for such positions. Germany and other European nations, who might be said to keep a keen eye on commerce, appeared to regard such appointments from a different point of view, and they took care to appoint only technically and commercially-trained men of the first order. The representative of Great Britain in foreign countries was too frequently the best available local man. In Norway and Sweden, for instance, England's representative was often some enterprising German merchant. The tendency in such a case was to supply the wants of the particular country through German channels. In connection with the University of Leeds there was a Chair of Economics and Commerce, and a diploma in connection therewith had been arranged, providing for the degree of Bachelor of Commerce. The training received at the University was sound, and at least two foreign European languages must be learned, preferably French and Spanish.

The resolution was carried unanimously.

A recent issue of the *Birmingham Daily Post* contains an interesting article on the status of the officers in the German army, from which we take the following paragraph:—". . . How unprofitable is the army as a career was shown by an incident of this year's Estimates debate. The Minister of War asked for a small vote for financing an officers' 'Labour Exchange,' already opened. The exchange was to find work for penniless retired officers. The Minister reported that immediately after the exchange was opened 850 officers applied for employment. Any employment short of manual labour is sought for, and almost any wage is accepted. In 1913 the Minister of War circularised chambers of commerce with the request that they use their influence with business men in order that retired officers might be given employment as clerks, &c. This expedient failed. The organised clerks protested against outside competition backed by the State. A service journal estimates that there are at present 3000 ex-officers practically without means who would accept any honest work; and that 4000 are already employed as clerks, overseers in industrial works, employees in State lotteries, and agents and order-hunters for champagne firms, furniture removers, and undertakers. From experience German citizens understand this state. I have myself had visits from seedy, but unquestionably military gentlemen, with cards bearing the legend *Leutnant ausser Dienst* (Lieutenant in Retirement), who brought invitations to buy or hire things. Often the proposed transactions would have yielded the ex-officer at most a few shillings. . . ."

The report for 1913, recently issued by the Inspector of Mines for the Liverpool and North Wales district (Mr. A. D. Nicholson), states that during the year the coal trade of the district was remarkably good, and regular work and higher prices were the rule. The slate industry continued to be in a very depressed condition, and metalliferous mining could hardly be regarded as being in a flourishing condition. Under the Coal Mines Act there were 218 mines at work, 83 metalliferous mines (some being on a very small scale), while about 386 quarries were worked regularly, but almost all the most important quarries showed a slight reduction in the number of persons employed. The total number of persons employed in and about the mines was 72,540, or an increase of 1483 as compared with the previous year. This constituted a record for the district. With regard to the total output, there was an increase of 959,584 tons, and the total quantity of coal and also of all minerals obtained, it is pointed out, has only been exceeded by the record year of 1907.

There was again an increase in the number of coal-cutting machines and conveyors at work. Machines increased by 33, and the output was 1,522,962 tons, an increase of 262,317 tons on the previous year's output.

The district was free from any large disaster. The total number of accidents reported was 328, causing the loss of 80 lives and injuries to 266 persons, showing a reduction on the figures for the previous year of 13 in the number of deaths and 39 in the number of persons injured.

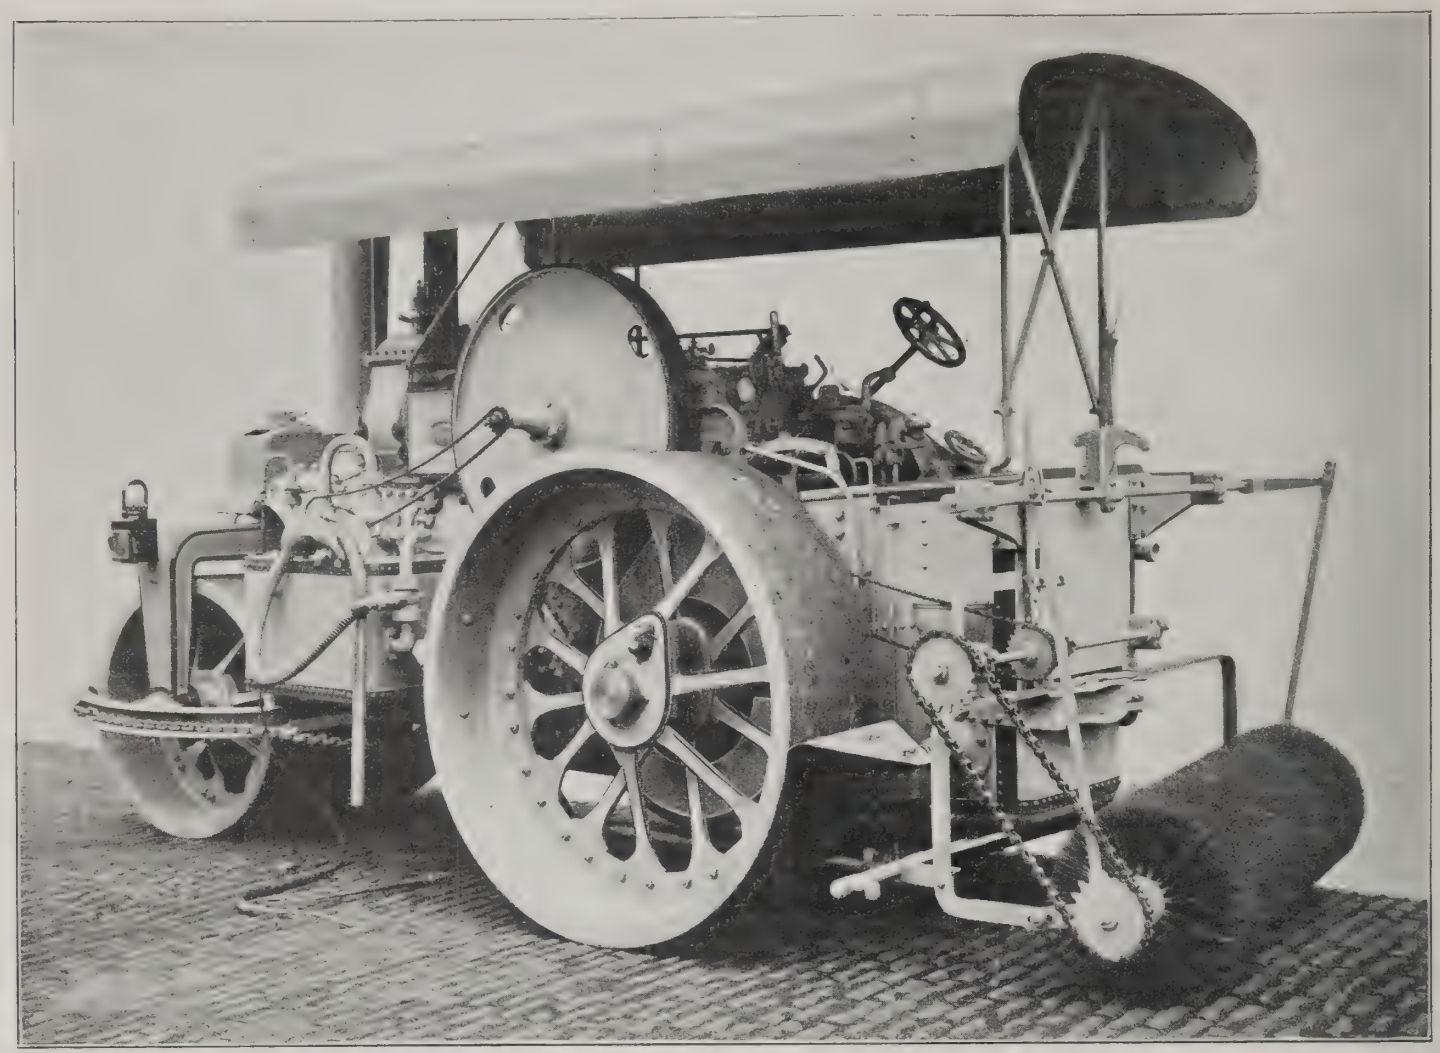
No legal proceedings were instituted during the year against owners, agents, or managers. The total number of prosecutions of workmen by owners amounted to 69, as compared with 25 in the previous year and 75 in 1911.

The Imperial Merchant Service Guild has been officially informed by the Director of the Labour Exchange at Rotterdam that the Municipal Council of that city has established at 4, Kaasmarkt—*i. e.*, in the centre of the shipping district—an institution for the employment of seamen. The institution will enable captains of British and other ships to obtain their crews in a quick and impartial way, thereby doing away with the services of shipping masters and boarding-house keepers, who hitherto obtained a living through placing seamen on board ships. The city of Rotterdam offers assistance to seamen of all nationalities entirely free of expense, looks after their general interests, and pays their advance notes in full without any charge whatsoever.

The new institution will also undertake to have the crews of ships signed on at the Consular office of the

COMBINED ROAD-ROLLER, TAR-SPRAYER, AND SWEEPER.

CONSTRUCTED BY MESSRS. JOHN FOWLER AND CO. (LEEDS), LIMITED, LEEDS.



nationality to which the ships belong, and to have the men taken free of charge on board at the proper time by officials in uniform. Such officials will also be on board up to the time the ship sails, during the day or night, and will be ready to supply substitutes if necessary. A small charge per man is to be made to owners.

Captain J. P. van der Does, an old commander of the Rotterdam Lloyd, is in charge of the institute, and has a staff of officials who have been chosen from amongst members of the nautical profession. At the head of the institution there is a general director and a special advisory committee consisting of shipping officials. One of the members of the committee is Mr. E. G. B. Maxse, Consul-General of Great Britain and Ireland. The consul-generals of other nations, steamship inspectors, and the Government dock-master of the port, Sir S. B. Ortt, and a number of other shipping officials of the port are also members. The institution is provided with a special reading and writing-room for the express use of captains and officers.

COMBINED ROAD-ROLLER, TAR-SPRAYER, AND SWEEPER.

In our issue of July 3 we referred to an exhibit at the Royal Agricultural Society's Show consisting of a combined 10-ton road-roller, tar-sprayer, and sweeper. This was to be seen at the stand of Messrs. John Fowler and Co. (Leeds), Limited, and is illustrated in the engraving above. In addition to embodying all the well-known features of Messrs. Fowler's road-rollers, this machine is fitted with a tank under the boiler barrel, of a capacity of 160 gallons of tar. This tank is furnished with a rotary pump chain-driven off the fly-wheel shaft. The pump is arranged with piping and cocks, so that it can either be used for filling the tank or for circulating the tar for mixing purposes, or for delivering it to six spraying-nozzles arranged on a transverse pipe at the back end of the machine. The tank is fitted with 60 ft. of heating pipe fed with exhaust steam from the cylinders, or live steam. The tar is delivered at the spraying-jets at a pressure of 300 lb. The machine may be used for tarring roads or for grouting new metal, the pressure being high enough to force the tar well into the interstices between the material. The machine will do a length of about 300 yards in five minutes. The engine is a compound, and is fitted for two speeds. The wheels have spring scrapers, and a water-sprayer is also provided. The brush does away with manual labour in sweeping the road. It is lifted clear of the surface previous to tarring.

Metallic Permanent-Way.—Our exports of metallic permanent-way do not appear to be making much progress; they amounted in June to 7828 tons, as compared with 7994 tons in June, 1913, and 10,258 tons in June, 1912, while in the six months ended June 30 they attained an aggregate of 56,141 tons, as compared with 61,955 tons and 56,807 tons respectively. In these latter totals shipments to British India figured for 47,002 tons, 46,037 tons and 43,710 tons respectively.

A Record Blasting for Europe.—On May 30 a blasting of iron ore took place at the iron-ore deposits of the South Varanger Company, Norway, to the works of which reference has been made in these columns on previous occasions. It was a question of blasting surface deposits, and by means of 17,000 kg. of dynamite 180,000 tons of solid ore were dislodged by one single blast. This is a record for Europe, and has, as far as is known, only been surpassed at the Panama Canal. The company is working at six places within the area of the deposits, and the ore is loaded on to railway-wagons by means of steam-shovels, the largest blocks being broken up by small charges. As a result of the blast referred to above some 30,000 tons of ore will be loaded per month until disposed of. The working at the South Varanger deposits and the various installations connected with it are being continually extended and increased. The concentration works are now finished, and will be able to receive and deal with some 150,000 tons of ore per month. During the month of June of the present year the new briquetting works, with a capacity of about 100,000 tons per month, commenced operations. The export has during the last few months—since March—exceeded 50,000 tons per month, and in that month it approached 70,000 tons. The export altogether is increasing at a very rapid rate; for 1912 it was about 250,000 tons, for last year about 450,000 tons, and for the present year it is expected to exceed 600,000 tons. Three steamers—two 11,000-ton ore-boats and one of 7000 tons—are regularly engaged in the Continental export traffic, more especially to Rotterdam, and five steamers, varying in size from 2200 tons to 5000 tons, are regularly engaged in the English trade; in addition, other boats are occasionally employed.

Fast Motor Vedette Boats for Greek Ministry.—Messrs. John I. Thornycroft and Co., Limited, have recently completed, to the order of the Greek Government, two fast motor-launches. The boats are driven by twin Thornycroft motors, with a combined power of 140 brake horse-power, giving a speed of over 15 knots. The over-all dimensions are:—Length, 50 ft.; beam, 8 ft. 3 in.; depth, 4 ft. 9 in. The machinery is situated amidships immediately forward of the wheel-house, with reverse-gear controls carried up through floor. Electric light is fitted throughout the boat, together with a powerful portable searchlight fixed on the roof of the wheel-house. A dynamo is run off one of the engine shafts, with accumulators stowed under the engine-room seats providing the necessary current. A small signal-mast is fitted on the fore-deck. The fuel is carried in two tanks, one under the floor of the wheel-house and the other right aft; together they have a capacity of 140 gallons. The two boats went through their trials with satisfaction to the officials.

The British Corporation for the Survey and Registry of Shipping.—The 1914 Register-Book and Rules of the British Corporation Registry, which has just been issued, gives a good indication of the steady growth of its operations, through the number of vessels which have been added to the Register during the past twelve months, and the additions to the list of owners who have adopted its classification for their vessels. Comparison with the Rules for 1913 shows a continuance of the Society's policy of maintaining the main features unchanged, but adapting details to meet experience. Evidence of this is found in the extension of the Rules for Periodical Surveys, which require an annual inspection of hatchways, casings, ventilators, and other protection to openings in the weather-deck, in addition to the ordinary special surveys, at intervals of four years. The construction rules relating to these parts have also been subjected to thorough revision, and have been considerably extended. These alterations should appeal to shipowners and underwriters as acting more directly towards greater security of life and property at sea. Several other minor modifications and amplifications have been made which are obvious improvements, and altogether the new volume is of great interest and value to the shipping community. The classification rules and tables come into force on August 1, and will supersede all other regulations previously issued by the Committee.

DEVELOPMENT OF INTERNAL-COMBUSTION ENGINES FOR MARINE PURPOSES.*

By M. DROSNE, of Messrs. Schneider and Co., Paris.

MESSRS. SCHNEIDER AND CO. have for some years specialised in the construction of oil-engines working on the Diesel principle. They concentrated their efforts at first on four-stroke-cycle engines specially designed for submarines for the French Navy or for foreign navies, but they very soon found that the two-stroke-cycle type might be of great use for engines of medium and of high power, both as regards reduction in weight and bulk, as well as for improvement in cyclic regularity. They therefore had no hesitation in studying and constructing that type of engine, together with the four-stroke-cycle one. Being, on the other hand, aware of the fact that it was not advisable to start on this new line without precise data on the advantages of the two-stroke cycle, derived from their own experience, they faced the heavy cost of erecting a couple of two-stroke-cycle engines at the works for trial purposes. These were vertical and each with a single cylinder. One had a stroke of 1 m. (3 ft. 3.37 in.), and developed 1200 h.-p. at 150 revolutions per minute. The other had a stroke of 0.46 m. (1 ft. 6.11 in.), and developed 300 horse-power at 400 revolutions per minute. These engines were to give an idea of the difficulties in regulating and running engines of large size or at high speed, so that means could be found to remedy any defects that might arise. The results enabled the constructors to start with confidence on the difficult solution of the problem relating to high-speed two-stroke-cycle light engines for submarines, and placed them in the foremost technical position to solve the problem of the use of large oil-engines for ordinary vessels. The experiments took place over a period of two years.

The two-stroke-cycle engines—like the four-stroke-cycle—are mostly light engines, of relatively high horse-power, built for marine work. On the other hand, the constructors did not lose sight of the development of heavy slow-speed engines (four-stroke cycle or two-stroke cycle) for cargo-boats, or of horizontal double-acting engines of high horse-power for land purposes. Their great experience in the construction of engines for land and sea placed them in such a position that they could safely set to work in executing their new designs, and to-day they are able to deal with all the intricacies of Diesel engines either of the land or marine type, two-stroke cycle or four-stroke cycle, vertical or horizontal, and single or double-acting. These engines have been highly successful, due to the excellence of construction and the materials used, the original design of the mechanism, and the care taken in perfecting them.

The following engines constructed at their works are worthy of note :—

(*a*) Eight engines of 360 horse-power each, four-stroke cycle, with eight cylinders, stroke 0.28 m. (11.02 in.), 400 revolutions per minute, for submarines of the Laubeuf type.

(*b*) Two engines of 700 horse-power each, four-stroke cycle, with four cylinders, stroke 0.48 m. (18.9 in.), 300 revolutions per minute, and two motors of 150 horse-power, four-stroke cycle, with four cylinders, 360 revolutions per minute, representing the main and auxiliary engines of the French submarine Amiral Bourgois.

(*c*) Two engines of 900 horse-power each, two-stroke cycle, with four cylinders, stroke 0.56 m. (22.05 in.), 230 revolutions per minute, for the cargo-boat France, belonging to the Société des Navires Mixtes, of Rouen.

(*d*) Two engines of 2400 horse-power each, two-stroke cycle, with eight cylinders, stroke 0.47 m. (18.51 in.), 350 revolutions per minute, for the French submarine Nereide.

(*e*) Six engines of 650 horse-power each, two-stroke cycle, with six cylinders, stroke 0.36 m. (14.17 in.), 400 revolutions per minute, for a French submarine.

(*f*) Eight engines of 1100 horse-power each, two-stroke cycle, with eight cylinders, stroke 0.37 m. (14.57 in.), 400 revolutions per minute, for submarines of the Laubeuf type.

(*g*) One engine for an electric generating set of 225-250 horse-power, two-stroke cycle, with three cylinders, stroke 0.36 m. (14.17 in.), 300 revolutions per minute.

It must be remarked that the submarines of the Laubeuf type come from Messrs. Schneider and Co.'s

naval works. Other engines in course of design or of construction may be mentioned :—

Four engines of 510 horse-power, four-stroke cycle, for submarines; one engine of 1500 horse-power for a cargo-boat; one horizontal tandem engine, double-acting, four-stroke cycle, of 2200-2600 horse-power, for an electric generating station; and two-stroke-cycle engines of 1100 horse-power for submarines.

Description of the Engines.

All the engines for submarines, whether four-stroke cycle or two-stroke cycle, are extra light. They are vertical, single-acting, with trunk pistons. The bed-plates and frames are of cast steel; the cylinders, which are either separate or cast with the frames, are of cast iron or cast steel with cast-iron liners. The cylinder-cover is of cast steel and carries (for four-stroke-cycle engines) the inlet-valve, the exhaust-valve, the injection-valve for fuel, and starting-valve. For two-stroke-cycle engines the air and exhaust-valves are replaced by scavenging-valves.

The crank and cam-shafts are of medium hard steel, which is tempered and annealed, and all the parts subjected to hard wear, such as cams, rollers, valves, pins, compressor-valves, &c., are in special steel. The air inlet and exhaust-pipes (the latter having water-jackets) are of sheet steel. All parts exposed to heat, such as the cylinders, cylinder-covers, exhaust-valve seats and exhaust-pipes, are water-jacketed. For the four-stroke and the two-stroke engines of large size the pistons are cooled by oil circulation. The crank-pins and crank-shaft bearings, the cylinders, and other main working parts have forced lubrication. The air-compressors, and for the two-stroke engines the air-compressors and scavenger-pumps (whether separate or forming part of the engine), are worked directly off the crank-shaft, which in many cases also works the oil-pumps for lubricating and cooling, as well as the pump for the water circulation. All these devices are practically the same for heavy engines, except that for the latter the bed-plates, frames and cylinders are of cast iron, and the pistons are provided with rods and cross-heads in engines of larger size.

Fig. 1, page 90, is a view of a four-stroke-cycle engine with eight cylinders, of 360 horse-power. Fig. 2 shows a two-stroke-cycle engine with four cylinders, of 900 horse-power; but two-stroke-cycle engines of 1100 horse-power with eight cylinders are constructed. Illustrations of one of the two-stroke motors of 900 horse-power on the cargo-boat France will be found on Plate XXIX. in Engineering of October 10, 1913.

Improvements in Working Parts.

Starting and Manœuvring Gear.—This has been applied to all the latest engines with a view to make starting and reversing as easy and as quick as possible. There are two cams for operating each valve on the main cam-shaft, one for ahead and the other for astern running. The rocking levers are, however, also controlled by cams fixed to a manœuvring cam-shaft, and these cams are adjustable, so that in certain positions the rocking-levers are thrown completely out of gear with the main cams. Thus one can see that by making adjustments to the cams on the manœuvring cam-shaft certain valve-levers will be thrown out of gear, whereas others will continue to bear on their main cams, so that according to the distribution required it is possible, when starting, to connect all the cylinders to the compressed-air supply, and then by adjusting the manœuvring cams to cut the air off from one or more of the cylinders and feed one or more with fuel as required. The adjustment to the manœuvring cams is made by revolving the cam-shaft, and one complete revolution of the shaft, worked by hand through a reducing gear, or by a servo-motor, is sufficient to start the engine. In the position corresponding to "stop," all valve-lever rollers are free, so that in order to change from ahead to astern drive all that is needed is to move the manœuvring cam-shaft to the "stop" position, and then to move the main cam-shaft longitudinally so as to place the "astern" cams under the valve-lever rollers, and then start the engine as explained above. This operation, which only takes 10 to 15 seconds, is made by successively rotating two small hand-wheels placed side by side one after the other. A safety device prevents the main cam-shaft moving longitudinally until the other cam-shaft is moved to the "stop" position. The whole arrangement is remarkably safe.

Valves.—The exhaust, air-inlet, and starting-valves (Fig. 3, page 99) are of the ordinary type, except that they are provided with a special device to prevent their falling into the cylinders if their rods break. The fuel-valves are either of the ordinary type—that is, direct-acting straight needles passing through a stuffing-box—or of the Swedish type, balanced and worked by rotation.

Fig. 5 (page 99).—This figure shows the cross-section of a cylinder belonging to a four-stroke-cycle engine, of eight cylinders and 510 horse-power. The fuel-valve casing is fitted at the bottom with a ball pulveriser and a multiple-hole diffuser. The ball pulveriser distributes the fuel in a very uniform manner with the air that is injected, though it offers but little resistance to the passage of that air owing to the balls being round. On the other hand, the multiple-hole diffuser allows the mixture to be sent in the required direction so as to distribute it evenly in the compression chamber, thus preventing it from being injected on to any one part that might get injured.

Fuel-Pumps.—One pump is provided for each cylinder. The plungers are specially constructed so as to render them perfectly tight. Each oil-pump is regulated by varying the amount of lift of its suction-valve, and the special feature of the gear for giving this variation is as follows:—(1) Hand regulation; (2) Regulation from the manœuvring cam-shaft (3) Regulation by over-speed. The hand-regulator, which works on a quadrant, serves to regulate the speed or load on the engine. The regulation from the manœuvring-shaft comes into play when starting ahead or astern, so that the pumps begin to work at the right moment only. Lastly, the speed-limit device acts so as to prevent racing.

Air-Compressors.—The air-compressors, Fig. 10 (Plate XXIX., of October 10, 1913), either independent or combined with the scavenger-pumps in the two-stroke-cycle engines, Fig. 4, page 99, are three-stage compressors and are worked direct off the crank-shaft. Their valves, which are of special steel, extra light and with short lift, are designed so as to give large openings. Their coolers, which are multitubular or of the coiled single-tube type, are fitted with large water-jackets, and ensure the most efficacious cooling.

Scavenging-Pumps. — According to the speed, the scavenging-pumps, which are worked off the crank-shaft, are provided with Hoerbiger valves or cylindrical slide-valves. Fig. 10, Plate XXIX., shows a pump fitted with Hoerbiger valves. Fig. 4 shows a cross-section of a pump with cylindrical slide-valves, and combined with its compressor, of which it forms the low and intermediate-pressure part. The slide-valves are driven by eccentrics fixed on the main cam-shaft. A sliding-sleeve with feather enables the cam-shaft to move longitudinally for ahead or astern drive without affecting these eccentrics.

Oil-Cooled Pistons.—The pistons are in two parts, joined together by long bolts, in which tubes carrying the cooling oil work telescopically (Fig. 8, Plate XXIX, and Fig. 5, page 99). The piston-head carries segments in cast iron or steel which bear lightly against the central part of the body of the piston. The telescopic tubes are provided at the bottom with a swivel joint, leaving them free to move in any direction, and maintaining a proper oil-tightness. The hot oil is returned from the piston to a filter, whence it is pumped by a special pump through a tubular cooler and back into the pistons.

Forced Lubrication. Splash-Guards.—The bearings of the crank-shafts and of the connecting-rods have forced lubrication. This is an excellent arrangement for efficient lubrication, but the splashing of oil by the cranks is undesirable for the following reason :—The oil thrown on to the cylinder-walls is sucked past the piston, which causes waste, and its partial combustion causes a smoky exhaust. These defects are now got rid of by means of special splash-guards. These, Fig. 8, Plate XXIX., are very efficacious.

Fig. 6 shows a section through one of the six cylinders of a 1500-horse-power engine for a cargo-boat, of the four-stroke-cycle type, and of low speed, which is now being designed. The pistons are provided with rods and cross-heads, and they are cooled by water circulation. The frames joining the cylinders to the bed-plate are made in two halves, bolted together and arranged so that one half can be easily removed, to allow the connecting-rod, piston, and cross-head to be taken out. The same arrangements apply to this motor as have been already described above.

THE CHARGING OF TWO-CYCLE INTERNAL-COMBUSTION ENGINES.*

By B. Hopkinson, M. Inst. C.E., F.R.S.

The performance of two-cycle internal-combustion engines is determined very largely by the efficiency or otherwise of the process of charging. In the course of less than one-fourth of a revolution the products of combustion resulting from the previous explosion have to be replaced as far as possible by the fresh charge of air, or of gas and air, which is blown in through the inlet-valves and drives before it through the open exhaust-ports the exhaust gases. Inevitably some mixing occurs, and some of the fresh charge, or of the scavenging air, passes away to the exhaust, and is wasted. On the amount of this waste depends very largely the performance of the engine. Its economy suffers to the extent of the waste of fuel. Its weight and cost are affected by the size of the charging-pumps, which must be big enough to deliver the whole charge of gas and air, including that which is wasted. The imperfection of the charging process is probably in large measure responsible for the fact that the two-cycle engine, in spite of the obvious advantage of double the number of working strokes, has not hitherto competed successfully in small sizes with the four-cycle type, and even in large sizes has achieved only moderate success.

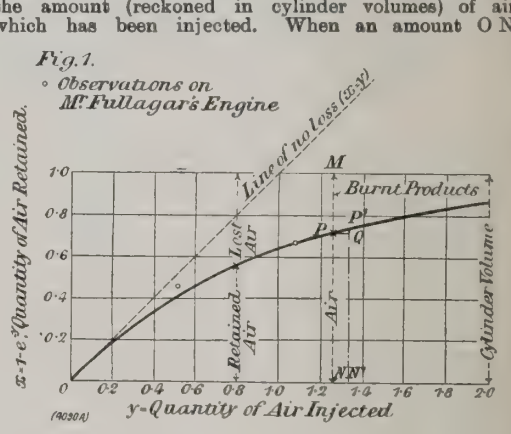
In considering recently the designs of certain two-cycle gas-engines, the author was struck by the almost complete absence of data of general application on which to base, in the case of a new design, a calculation of the size of pumps required to give a certain mean pressure and a prediction of the economy which may be expected. Little or nothing has been published as to the amount of the loss to exhaust which occurs in existing engines, and there is no theory to guide designers in the use of such data as exist on this point or may become available. In the present paper an attempt is made to provide a working theory of this kind, some experimental confirmation is given of it, and methods are suggested for getting more information.

In the course of the charging process, for each unit of volume of air or mixture which enters at the inlet an equal volume of the gas near to the exhaust-ports will be driven out through those ports, which gas will consist partly of burnt products and partly of air which has mixed with the products. It is here assumed that the pressure in the cylinders during the admission period is that of the atmosphere; the effect of the disturbance of this pressure by throttling at the exhaust-ports, and by the inertia of the gases in the exhaust-pipe will be considered later. Denote by z the proportion of air by volume contained in the exhaust gases. This will be the same as the proportion which is contained in the cylinder contents near to the exhaust-ports at any state of the charging. For this purpose z is not the volumetric proportion determined by an ordinary analysis; it is the volume, reckoned at atmospheric pressure and at the temperature of the air as it comes in, contained in a cubic foot of the cylinder volume; the balance $1-z$ consists of burnt products from the previous explosion, whose volume is, for this purpose, reckoned at the temperature of those products before charging began. Obviously z will increase from zero as charging goes on, and will approach, but never reach, the value unity; at first, when very little air has been put in, the exhaust gases contain no air; when a large quantity has been blown through, the exhaust is almost pure air. The total amount of air lost in charging will be equal to the volume delivered (denoted by z) multiplied by the average value of z, and is readily calculable if this quantity is known at every stage. The amount of air retained in the cylinder is equal to y minus the loss; this will be denoted by x.

Two cases admit of very simple treatment. The first is the ideal case of perfect stratification. The air simply drives the burnt gases before it without mixing with them at all, and there is no loss until the amount of air exceeds the cylinder volume. It is quite certain that this condition is never even approached in practice. Probably the first two-cycle engine ever built, that made by Dr. Dugald Clerk in 1880, came nearer to attaining this ideal condition than any which has been made since. Dr. Clerk, who thoroughly appreciated the necessity of getting as much stratification as possible, used a very long conical combustion-chamber. Even so, there must have been a good deal of mixing, and in modern high-compression engines (the compression-ratio in the Clerk engine was 3) such a construction is impossible.

The second case represents much more nearly what actually happens. Suppose that instead of complete stratification there is no stratification at all—suppose the mixing so complete that the cylinder contents are at every instant of uniform composition throughout. Here again it is possible to calculate the proportion lost up to any stage with complete certainty and accuracy. The quantity z now represents not only the proportion of air in the gas which is going into the exhaust at any stage, but also the proportion then present in the cylinder as a whole. It is convenient in these calculations to take as the unit of volume the whole volume of the cylinder, and x the volume of air which has been retained in the cylinder then represents also the proportion of air in the whole cylinder contents, so that in the case now under consideration $z = x$. In Fig. 1 x is plotted against y, the amount (reckoned in cylinder volumes) of air which has been injected. When an amount O N

Fig. 1.



has been injected, the air present in the cylinder P N, the remainder P M being burnt products. The effect of adding the further dose of air N N¹ is to expel at the exhaust the quantity of air $\frac{P N}{M N} \times N N^1$. The balance remains in the cylinder, increasing the quantity of air there by $P^1 Q = \frac{P M}{M N} \times N N^1$. So the curve can be constructed step by step. It is the well-known exponential curve whose slope at any point is equal to the ordinate P M. The relation between x and y (of course, easily obtained mathematically) is $x = 1 - e^{-y}$.

In many engines now in use the mixing is probably fairly complete, and the simple formula just given represents fairly accurately what occurs. Such are short-stroke Diesel engines with valves in the cylinder-cover, and probably also the double-ported engines having the inlet-ports opposite the exhaust-ports and a deflector-plate on the piston. In engines having relatively longer cylinders, such as the Oechelhäuser, there is some stratification of the cylinder contents; but even here the effects of stratification are probably not very great. They are of the nature of a correction, and before discussing this correction along with others, the necessity of which will appear later, it will be convenient to compare the simple formula with results actually obtained from an engine in the course of some recent trials conducted by the author for the Fullagar Engine, Limited, and then to give some illustrations of its application to other papers.

Tests on Mr. Fullagar's Engine.

The engine in question was built to the designs of Mr. H. F. Fullagar. It represents an important de-

* Paper read at the joint meeting of the Institution of Naval Architects, the Institution of Engineers and Shipbuilders in Scotland, and the North-East Coast Institution of Engineers and Shipbuilders, at Newcastle-on-Tyne, July 8, 1914.

velopment in large-power gas-engines, and has several features of great interest, but, as Mr. Fullagar will be describing it himself, it is only necessary to give here such details as bear on the subject of this paper. It has four vertical cylinders of the Oechelhaüser type, coupled together in pairs, the upper piston of one being coupled by diagonal rods to the lower piston of its neighbour, in the manner invented by Mr. Fullagar. The leading dimensions of each cylinder are given in Fig. 2. The air-ports (there is only one set of admission-ports) communicate with a large receiver, to which air is delivered by an electrically-driven fan. Coal-gas was used in these trials, and was admitted by a piston-valve at the centre of the cylinder. The valve was opened 5 deg. of crank angle before the exhaust-ports closed, and remained open for 36 deg. crank angle. The coal-gas was delivered at high pressure by a reciprocating pump.

The verification of the formula above given required the accurate measurement (1) of the total quantity of air delivered to the engine per minute, and (2) of the proportion of that air retained in the cylinder.

1. *Quantity of Air.*—A diaphragm with a circular hole was inserted in the air-delivery pipe, between the fan and the engine, and the drop of pressure measured by means of a water-gauge. The diameter of the air-pipe was 18 in., that of the hole in the diaphragm 9 in. The current of air through the diaphragm was nearly uniform, the pulsations caused by the engine being nearly damped out by the large air-receiver. The velocity of the air through the hole was calculated according to the usual formula, assuming 0.62 as the coefficient of discharge. The coal-gas was also metered, and the quantity of coal-gas used, together with an analysis of the exhaust gases, gave an independent measure of the amount of air used. The quantity of air delivered to the engine was probably determined correct within 3 per cent.

2. *Proportion of Air Retained.*—For determining this samples were taken of the contents of all four cylinders, and analysed. The average proportion of carbon determined in the samples was compared with the proportion in a sample of the exhaust gas taken simultaneously. The ratio of the two carbon contents is equal to the ratio of the total air delivered to the air retained in the cylinder, $\frac{y}{x}$ in our notation.

For the purpose of collecting the samples of the cylinder contents, a pipe of very small bore was screwed into a hole drilled in the sparking-plug. The other end of the hole was closed with a nipple having a small hole in it. The pipe communicated with the sampling vessel, into which it delivered the gas slowly, a small quantity coming in at each explosion. The result of this procedure is that the sample consists partly of a mixture of unburnt gas and air blown through the pipe during the compression stroke, and partly of burnt gases which come through during the expansion stroke. Usually the proportion of burnt to unburnt was about 2 to 1. As the coal-gas admission-valve is opposite the sampling-hole, both being at the middle of the length of the cylinder, the tendency of the method is to collect samples which are a little too rich in coal-gas. But it is believed that the error so caused is not large. The greater part of the sample comes through while the pistons are near the in-centre, by which time any stratification of the coal-gas will in large measure have disappeared, and will moreover be of less importance because of the compression of the cylinder contents.

Samples were taken from all four cylinders simultaneously, and after absorbing the CO_2 the combustion of the residue was completed over palladium, and the further yield of CO_2 obtained. The total CO_2 gave the proportion of coal-gas to air in the cylinder contents. A simultaneous analysis of the exhaust gases gave the proportion of coal-gas to air delivered to the engines. A check was obtained by estimating the oxygen in the exhaust and in the cylinder contents. The analyses were made for the Fullagar Engine, Limited, by Dr. Mechie and Mr. Hill, of the Wallsend Laboratories. Great care was taken by these gentlemen to eliminate all errors in the estimations, and the author believes that, thanks to their labour, the figures now given are of an order of accuracy rarely attained in a commercial trial.

The following is a summary of the results obtained in two trials, in one of which the volume of air delivered to each cylinder per stroke was about equal to the cylinder volume, in the other about half. In the first case the engine had to be run slow, as the fan would not at the normal speed deliver a sufficient volume of air to give a cylinder-full per revolution:—

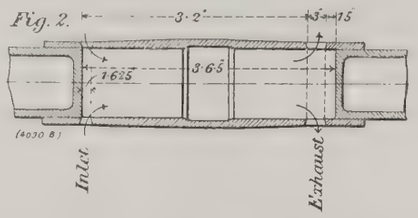
Trial.	Ia.	Ib.	II.
Speed .. .. revolutions per minute	200	200	250
Air per cylinder per revolution (by diaphragm) .. .. cub. ft.	2.70	2.70	1.42
Air per cylinder per revolution (by gas-meter and exhaust analysis) .. cub. ft.	2.86	2.86	1.38
Coal-gas per cylinder per revolution (by meter) .. .. cub ft	0.189	0.182	0.163
Air delivered to engine (exhaust Coal-gas analysis)	15.1	15.7	8.45
Air in cylinder contents (analysis, Coal-gas mean of four cylinders)	9.4	9.45	7.35
Air retained, per cylinder per revolution cub. ft.	1.78	1.72	1.20

The volume of the cylinder when the pistons are at the out-centre is 2.75 cub. ft. When the inlet-ports are just closed it is 2.50 cub. ft. Having regard to the dwell of the pistons near the out-centre, the mean volume during the period of injection will be nearer to the former figure; take it as 2.65 cub. ft. Dividing this volume into the volumes of air given on lines 3 and 7 of the above table we get the value of y and x. They are tabulated in the following table, together with the corresponding values of x calculated from the formula.

—	Ia.	Ib.	II.
y = air delivered per cubic foot of cylinder volume	1.08	1.08	0.52
x = air retained per cubic foot of cylinder volume	0.67	0.65	0.45
Calculated value of $x\,(=1-e^{-y})$	0.66	0.66	0.405
$y-x$ (measured)	0.41	0.43	0.07
$y-x$ (calculated)	0.42	0.42	0.115
Percentage of air lost to exhaust (measured)	38	40	13.5
" " " (calculated)	39	39	22

It will be seen that there is rough agreement between the calculated and measured figures, sufficient at any rate to justify the use of a simple supposition of complete mixing as a first approximation to what occurs. On the other hand, the deviation with the smaller amount of air is too great to be ascribed to errors of observation. The observed loss of air is only about two-thirds of the calculated loss. This shows that there are disturbing factors which must be taken into account as corrections to the simple theory. In trials Ia. and Ib. these connections apparently neutralise each other, producing, as it happens, almost exact agreement. Before dealing with these corrections, it will be convenient to give one or two simple illustrations of the application of the theory to practical cases.

Fig. 2.



(*a*) Diesel engine, stroke equal to bore, or slightly greater; inlet-valves in cylinder cover. This is a case in which the mixing will be nearly complete. Suppose that the volume of the air-pump is $1\frac{1}{4}$ times the total cylinder volume (including clearance space). The volume of air delivered, reckoned at the temperature of delivery, will be approximately that of the pump, the rise of temperature due to the pumping work compensating for the volumetric inefficiency of the pump. Hence $y = 1.25$ and the volume of air retained (P N in Fig. 1) is $x = 1-e^{-1.25} = 0.71$. The volume wasted ($y - x$) is 0.54, or 43 per cent. of the amount pumped. The cylinder contents consist of a mixture of 0.71 air at 40 deg. to 50 deg. Cent. (temperature in air-delivery pipe) and 0.29 of burnt products at perhaps 500 deg. Cent. The scavenging is far from complete, and the charge would be rather hot and the flame temperature correspondingly high, necessitating a low mean pressure in order to avoid over-heating. It may be added that no substantial improvement can be effected in this respect except by the use of excessive quantities of air. For instance, it will be seen from the diagram that to reduce the amount of burnt products left in the cylinder to 15 per cent. the air-pump must be nearly twice as big as the cylinder.

(*b*) Gas-engine, with separate gas and air-pumps, using producer-gas. In such an engine the pumps and admission-valves or ports would be arranged so that as far as possible the air goes in first, the gas following it. Thus in the Oechelhaüser the air-ports open first, and a large part of the air is discharged through them before the gas-ports open. Then the gas comes in, mixing with the remainder of the air. The amount of air coming in with the gas in any case can be calculated roughly beforehand from the size of receivers and the size and position of gas and air-ports; but such calculations are apt to be much upset by the exhaust back-pressure, whose efforts are difficult to allow for, and will vary in different cases according to the length of the exhaust-pipe. For purposes of illustration, we will assume that at full load the volume of air passing the air-ports before the gas-ports open is half the cylinder volume; and that this is followed by quarter cylinder volume of gas and the same quantity of air, and that no air enters after the gas-ports are closed.*

The volume of mixed gas and air is half the cylinder volume. Hence $y = \frac{1}{2}$, and the amount of mixture retained in the cylinder per cubic foot of its volume is $x = 1-e^{-0.5} = 0.394$. The proportion of the pumped gas which is retained and burnt is $\frac{x}{y} = 0.79$, and the balance (21 per cent.) is wasted to exhaust. Assuming the engine to have a compression ratio of 6.5 (ratio of cylinder volumes at out and in-centre), it would give an indicated efficiency on the basis of the gas actually burnt of 0.37 or 0.38, say 0.375. The quantity of gas retained and burnt per cubic foot of stroke volume is $0.79 \times 0.25 \times \frac{6.5}{5.5} = 0.233$ cub. ft. If the gas has a lower calorific value of 140 British thermal units per cubic foot at atmospheric pressure and at the temperature in the receiver, the indicated mean pressure will be $0.375 \times \frac{0.233 \times 140 \times 778}{144} = 66$ lb. per sq in., which is a little above the normal figure for an engine of this type. Allowing a mechanical efficiency of 83 per cent., the practical efficiency (ratio of brake power to the lower heat-value of the whole of the gas pumped) will be $0.83 \times 0.79 \times 0.375 = 0.246$, equivalent to about 10,400 British thermal units per brake-horse-power hour.

In practice two-cycle gas-engines do a little better than this, though at the high mean pressure of 66 lb. per sq. in., it is doubtful whether any of them could be relied on to produce a brake-horse-power hour for much less than 10,000 thermal units. The Oechelhaüser engine with its long cylinder gets the benefit of some stratification. In the Körting the admission valve is timed so that it closes after the exhaust-ports, and some of the charge is thus trapped without any possibility of getting out. On the other hand, in both cases these favourable factors are apt to be neutralised by the exhaust pressure holding up the scavenging air. But broadly speaking, and subject to corrections of this nature, which, on the whole, are small, the simple theory leads to conclusions which are in accord with practical results. It may be noted in this connection that the Fullagar engine, in which there was no waste of gas at all, showed an indicated efficiency of 0.376, and a brake efficiency of 0.30; and the latter figure would reach 0 31 if the mechanical efficiency were raised to the normal figure for these engines by the use of a more economical method of serving the engine with air.

Effects of Stratification.—In the simple theory of the charging process which has been discussed, it is assumed that at every instant during the period of admission the cylinder contents are homogeneous in composition, and that their pressure is that of the atmosphere. In fact, there is in all engines some stratification of the cylinder contents, the portions near the exhaust-ports being poorer in air and richer in burnt products than the average. There is also in all cases some throttling in the exhaust-ports and exhaust-pipe, and inertia effects in the exhaust-pipe, in consequence of which the pressure in the cylinder varies during the admission period. The effects of these two factors will now be considered, beginning with stratification. Suppose that y represents, as before, the volume of air which has been delivered through the inlet-ports at any stage, and x the volume which has been retained in the cylinder, $y - x$ having been wasted through the exhaust-ports. These volumes are reckoned in terms of the total cylinder volume taken as unity, and x is therefore the average proportion of air (by volume) in the cylinder contents. These contents are now, however, not of uniform composition, but near the inlet-ports they are richer in air than the average, and near the exhaust-ports poorer. Thus a cubic inch of air delivered through the inlet now displaces and drives through the exhaust a cubic inch of gas containing a proportion z of air, where z is less than x. The full discussion of the relation between z and x—that is, of the amount of stratification—is beyond the scope of this paper; it will suffice to state here that there are good *à priori* grounds for the supposition that in practical cases it is given by an expression of the form:—

$$z = x\left\{1-\lambda(1-x)\right\}$$

where λ is a constant depending on the engine (proportions of cylinder, size and shape of ports, &c.). It will be seen that this formula satisfies two necessary conditions: the one that at the beginning of injection the exhaust shall contain no air ($z = 0$ when $x = 0$), the other that when a large quantity of air has been blown in, so that the burnt products have been nearly all cleared out, the exhaust shall be practically pure air ($z=1$ when $x=1$).

The constant λ, which is characteristic of the engine as regards stratification, I propose to call the "stratification constant." The greater its value the greater is the amount of stratification; and when $\lambda = 0$ there is no stratification, for then $z=x$; that is, the proportion of air near the exhaust-ports is equal to the average proportion throughout the cylinder.

Once the proportion of air near the exhaust-ports (z) is known in terms of the average composition (x), the relation between the quantity of air retained (also x) and the total quantity injected (y) can be obtained with mathematical certainty. For the relation between z and x given above, it takes the form:—

$$x = \frac{1 - e^{-(1+\lambda)y}}{1 + \lambda e^{-(1+\lambda)y}}$$

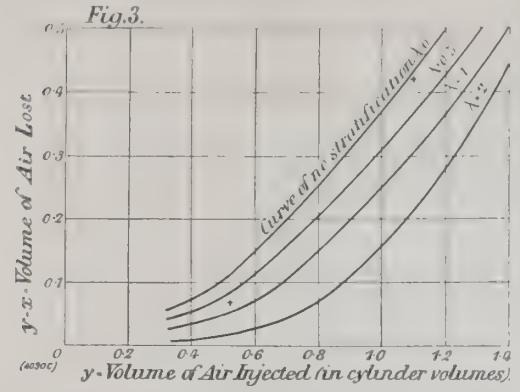
This formula applies to such amounts of stratification as are likely to occur in practice, for which λ will not usually exceed 1. For larger values of λ the expression for z in terms of x obviously ceases to be accurate, since it would take a negative value unless x is nearly equal to 1. The more accurate relation between x and z, to which the simple equation given above is an approximation, leads to a somewhat more complicated formula for x in terms of y, which it is unnecessary to give here, as it is not required in any practical case.

In Fig. 3 are plotted the curves of loss $(y-z)$ calculated from this formula for various values of λ. If this constant is known for the type of engine under consideration, the corresponding curve gives (subject to any correction for the effects of exhaust-back-pressure) the amount of air wasted out of any given quantity injected. It is to be

* With a perfectly free exhaust, this distribution of air and gas is possible in the ordinary design of the Oechelhaüser engine; but the author is of opinion from data in his possession that in ordinary practice the distribution is not so good. Cards taken from the receivers in one case, which is probably typical of many, show that the exhaust pressure had not fallen to atmosphere when the air-ports opened, so that the air was held up, and more of it went in along with the gas than is here assumed.

noted that in most cases λ is not much greater than unity, and a comparatively rough guess at its value, based on experience with similar engines, will give results good enough for practical purposes.

Fig. 3.



The points determined from the tests on Mr. Fullagar's engine are noted on the same sheet, from which it will be seen that the lower point falls between the curves corresponding to $\lambda = 0.5$ and $\lambda = 1$, while the upper, as already indicated, falls near the curve $\lambda = 0$.

Experiments with a Water Model.

The phenomenon of stratification can be studied very conveniently by means of a model of the engine cylinder in which water is used instead of air. The model can be made to scale, of sheet iron, and is provided with an admission-valve at the lower end, which can be opened and closed by hand. Through the valve the cylinder communicates with a large chamber containing water with an air-space above, whose volume is equal to or greater than that of the water. Air is pumped into the chamber until the pressure is 10 or 15 lbs. per sq. in. The exhaust-ports at the upper end of the cylinder are permanently open, and discharge into a channel, whence a shoot leads to a tank. The cylinder is filled up to the edge of the exhaust-ports with brine containing a known proportion of salt; this corresponds to burnt products. In making an experiment the valve is rapidly opened and closed by means of a handle and crank, this operation taking in an ordinary case about 1 second. The water from the chamber (which corresponds to the air in the engine) rushes through the inlet-valve and displaces the brine. Samples of the contents of the cylinder and of the exhaust-tank are then analysed for their contents of salt, and from the analysis the quantity of pure water which has passed out through the exhaust along with the brine can be estimated. The experiment corresponds, in fact, with that already described as having been made on Mr. Fullagar's engine, in which simultaneous analyses were made of the cylinder contents and of the exhaust gases.

The use of water models for ascertaining the behaviour of air is familiar to those who are concerned with aeronautics. The resistance of an airship, for instance, can be ascertained by towing a model in a water-tank. Theory, which has been confirmed by experiments of many different kinds, shows that the motions of the two fluids will be dynamically similar if the velocities and the linear dimensions are so related in the two cases that $\frac{VL}{\nu}$ is the same for both, ν being the viscosity. For air the value of ν is about 13 times as great as it is for water. Hence, if the dimensions of the model and ship are the same, the motions will be similar if the model is towed $\frac{1}{13}$ of the speed of the ship.

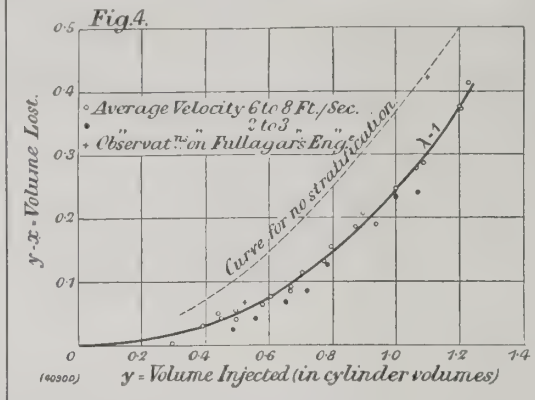
In the case of the engine cylinder the matter is more complicated, because the hot burnt products which the cylinder at first contains have greater viscosity and less density than the air which displaces them. Moreover, owing to the varying back-pressure in the exhaust, changes of density occur in the cylinder contents which can have no counterpart in the water model. But subject to these points there cannot be any question that the law of dynamical similarity will apply equally to this case. That is to say, if producer-gas is injected into a cylinder containing cool air (as happens if there has been a previous scavenging charge) and possessing a completely free exhaust, the loss will be precisely the same as the loss of water in the water model when the same quantity of water is injected at $\frac{1}{13}$ of the velocity. The period of injection of the water will be 13 times as great as that of the gas; thus the whole operation can be done slowly by simple mechanism.

Fig. 4 shows the results of a large number of experiments made on a full-size model of Mr. Fullagar's engine The curve is that corresponding to the formula given above for the case where $\lambda = 1$. It will be observed that within errors of observation the observed points agree with this curve. This is a satisfactory confirmation of the theory on which the formula is based. It will also be noticed that the velocity of injection varies widely in different experiments, but that there is apparently no considerable difference between high and low velocities as regards the loss to exhaust. This fact is of some importance, because it follows from it that similar variations in the viscosity of the fluid would have a like small effect.

On the same diagram are marked the two points showing the loss of air actually occurring in Mr. Fullagar's engine. It will be seen that in both cases the loss in the engine is greater than in the model, though the difference is not very great in the case of the smaller quantity of air. The differences must be due to one or both of the two factors which have been mentioned as not represented on the model; that is, the difference in viscosity and density between the air and the burnt products which it displaces, and the varying pressure in the cylinder. The effect of viscosity is certainly small; that of density may be considerable. But in the author's view it is probable that the important cause of the difference is the varying pressure, which is considered in greater detail in the next section.

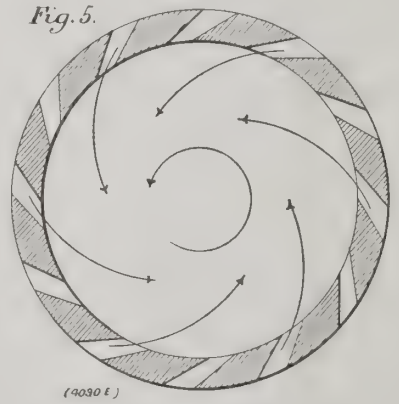
It is obvious that the use of water models cannot be relied on as a means of quantitative investigation until further comparisons have been made between engines and their models, and even then the disturbing factor of exhaust pressure complicates the interpretation of the results. But the author believes that it promises to be a

Fig. 4.



useful way of comparing, with little expense and trouble, the properties of different forms of cylinder and of ports and valves as regards stratification. For instance, it would appear from experiments of this kind which the author has made that a cylinder like the Oechelhaüser, whose length is perhaps three times its diameter, is much better from this point of view than a cylinder of one-third that length, such as a short-stroke engine with admission-valves in the cylinder cover. In the shorter cylinder none of the many devices that the author has tried with the view of directing the motion of the incoming air have availed to produce any stratification. But in the larger cylinder it would appear that such an

Fig. 5.



arrangement as is shown in Fig. 5, whereby a whirling motion is given to the air, has the effect of substantially reducing the loss.

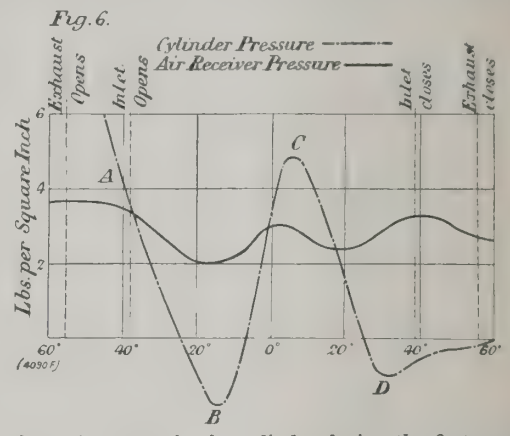
Effect of Varying Pressure in the Cylinder.

Both the simple theory and the discussion of the correction of that theory for stratification rest on the assumption that the pressure in the cylinder is atmospheric during the admission period. As a matter of fact, in any actual case this pressure will vary, the variations being determined partly by the throttling effect of the exhaust-ports, but mainly by the inertia of the column of gas in the exhaust-pipe. The surging of this column of gas causes the pressure in the exhaust-pipe near the engine to rise and fall in a periodic manner, the period depending on the length of the pipe. A full discussion on the amount and nature of these variations of pressure is outside the scope of this paper, and all that will be attempted is a short consideration of their effects, in one or two simple cases, on the charging of a two-cycle engine.

It seems probable that those pressure variations which are likely to occur in practice will cause increased loss to exhaust. For instance, it may happen that the exhaust-pipe pressure is rising when the admission-ports or valves are first opened, with the result that at first the injection of a cubic inch of air will not be accompanied by the discharge of an equal volume of mixed air and burnt products, but a less volume will be discharged. When at a later stage the exhaust-pipe pressure falls to atmosphere or (it may be) below atmosphere, the excess volume which had been held up in the cylinder will be discharged. The proportion of air in the gas which then goes out corresponds to the whole, or nearly the whole, amount which has been injected, and will be greater than it would have been had the exhaust come out as fast as the air went in. To take an extreme case, suppose that half of a cylinder volume of air is put in without anything going out of the exhaust-ports at all. The cylinder contents will then consist of one volume of burnt products more or less thoroughly mixed with half a volume of air, the pressure of the whole being $1\frac{1}{2}$ atmospheres. Now suppose that the exhaust-pipe pressure falls to 1 atmosphere. The accumulated cylinder contente, now well mixed up, will at once escape. The volume of gas passing out will be half the cylinder volume, and it will consist of air and burnt products in the proportion of 1 to 2. Thus the quantity of injected air which is lost will be $\frac{1}{3} \times 0.5$ or 0.17 cylinder volume. Reference to the curve, Fig. 1, will show that if the pressure had been uniform, the quantity lost (in the absence of stratification) would be 0.105. This, of course, is an extreme case, which could not arise in practice, but it shows the tendency of a high exhaust pressure at the beginning of admission to increase the loss of air.

The actual pressure variations in the cylinder of the Fullagar engine at a speed of 250 revolutions per minute are shown in Fig. 6. It will be seen that here the surging in the exhaust-pipe is of such a character as to produce

Fig. 6.



a drop of pressure in the cylinder during the first part of the admission period (A to B). During this period the gas is going out quicker than it comes in, and the exhaust consists mainly of burnt products mixed with a little air. Then at B the pressure begins to rise, and the air accumulates in the cylinder. At C the pressure falls rapidly, and the accumulated cylinder contents, which have had plenty of time to mix, are rapidly discharged, thus reproducing at this stage the conditions described in the last paragraph. Moreover, at C the cylinder pressure is higher than the air pressure, so that some of the cylinder contents (which still contain a large proportion of burnt products) will back into the receiver; some of the contents of the exhaust-pipe must also at this point come back into the cylinder. A quantitative estimate of the effect of the variations on the loss of air could be made by the use of the principles enunciated earlier in this paper, but would be a long and complicated piece of work. It will be sufficient to observe that the general result must be to increase the loss. The holding-up of the air and the backward and forward flow in the middle of the admission period will mix up the air and products of combustion, and will destroy the stratification which would otherwise exist. The author believes this cause to be sufficient to account for the difference between the results obtained with the water model and with the engine.

Though the theory of the charging process which has been suggested in this paper cannot be regarded as completely proved as regards details, the author has ventured to bring it to the notice of those interested in two-cycle engines in the hope of eliciting from them more facts about the loss to exhaust. It is to be regarded as a working hypothesis which may prove useful in the interpretation of data, but which will probably require modification in its details as more facts are accumulated. This remark applies more particularly to the corrections for stratification and for varying exhaust pressure. The simple theory based on the assumption of complete mixing and uniform cylinder pressure is, in the author's opinion, a very fair first approximation, which will give results of sufficient accuracy in most practical cases, and as such he hopes that it may prove of use to designers.

The author wishes to express his gratitude to the Fullagar Engine Company, and to Mr. Fullagar, for permission to make use of the results obtained in the trial of their engine, and for the facilities which they provided in the course of that trial for making measurements, the commercial value of which was not immediately obvious. He is also much indebted to his assistant, Mr. Bird, for his care and zeal in carrying out many experiments and designing apparatus used in connection with this paper.

English Enterprise in Sweden.—Extensive surveying and investigating work is at present going on in Iämtland, Sweden, for account of an English syndicate. The two localities in question are Karberget and Ankarvattnet; the former, close to the Ström valley, contains vast deposits of magnetic ore and copper ore, also cornite. At the Ankarvattnet there is a sulphur ore, containing copper, the vein being about 40 metres broad, and the ore containing about 45 per cent. of sulphur, which means that it is well suited for export. The value of the Ankarvattnet, should the calculations of the experts prove correct, will certainly be very considerable, the more so as a place within the northern frontier, and about 6 miles distant, is about to have railway connection with a Norwegian port.

BALANCING OF INTERNAL-COMBUSTION ENGINES.*

By H. F. FULLAGAR, M.A. (Cantab.), of Newcastle-on-Tyne.
Communicated by WILLIAM HANNING, Member, of Paris.

THE problem of balancing internal-combustion engines is in general much more difficult and complex than the corresponding problem with steam-engines. The adoption in the former case of the single-acting cylinder and trunk-piston generally necessitates wider crank-angles than with steam. If, on the other hand, a larger number of cylinders are employed, vibration arises owing to the increased length and flexibility of crank-case or framing. A further difficulty in comparison with steam practice arises from the sudden and violent increase of pressure when the charge is fired by a spark, which has nothing comparable in the gradual admission of steam pressure to the piston, whilst when the charge is fired by high-compression the compression stroke produces a severe reversal of torque in the crank-shaft and reversal of side-thrust between the piston or crosshead and its guide. But while on the one hand the difficulties of balance are greater in the case of the internal-combustion engine, the need of perfection of balance is also greater, owing to the purpose for which the internal-combustion engine is particularly applicable.

In marine work a very high standard of balance has been set by the steam-turbine; for motor-car and aviation purposes an even higher standard is required, for the following reason:—When an engine with a very light framing is mounted on a light fuselage, the inertia forces, which are relatively very large, unless well balanced amongst themselves, will communicate vibration to the whole machine. Long-distance flying is at present largely a matter of endurance of the pilot, and vibration, apart from its effect upon the engine and fuselage, induces fatigue and saps the nerves of the pilot and observer.

Absolute freedom from vibration involves balance of two kinds—balance of mass and balance of impulse.

Balance of Mass.—Dealing first with the balance of mass: this requires that if the engine be driven by some external source, the inertia forces due to the acceleration of the rotating and reciprocating parts neutralise each other and have no external resultant. Balance of mass is so well understood by members of this Institution that it is necessary only to notice very briefly the degree attained with ordinary constructions of internal combustion engine. Balance of the rotating members, the crank-shaft and cam-shaft, presents, of course, no theoretical difficulty, provided the crank case is sufficiently rigid to resist the reactions set up.

The inertia forces of the reciprocating parts are of two kinds: primary forces, such as would result if the piston had simple harmonic motion, that is, if the connecting-rod was of infinite length; and secondary forces, due to the additional motion resulting from the finite length of the connecting-rod. This secondary motion is almost exactly simple harmonic in character, but has double the frequency. Perfect balance of both primary and secondary forces can together be secured only by placing connecting-rods on opposite sides of the crank-shaft (Figs. 1 and 2). If, as usual, the crank-shaft revolves, the connecting-rods must be attached to opposite cranks; but if the cylinders revolve, both connecting-rods can be attached to a single crank (Fig. 3). All three constructions can, however, have but limited application.

The ordinary motor-car engine with four cylinders operating upon the four-stroke cycle necessarily has its crank in one plane, 180 deg. apart, in order to give reasonable uniformity of impulse. In this case the secondary forces are wholly unbalanced. When the plane of the cranks is horizontal the connecting-rod has moved the piston to below mid-stroke by the amount a, Fig. 4, which, if the length of the connecting-rod be four times the crank radius, amounts to one-sixteenth of the stroke. As this displacement occurs twice per revolution, and affects all four pistons, the secondary forces set up are equivalent to the inertia of a single piston moving the whole stroke, but acting with double the frequency. With a connecting-rod of the length of five cranks, the secondary inertia force is four-fifths of this amount. When two such sets of four cylinders are placed together in the "V"-type engine, the secondary forces of each set are unbalanced, and their resultant is 40 per cent. greater than either, and acts in a horizontal plane, Fig. 5.

The secondary forces of the four-cylinder engine, Fig. 4, result from the fact that the common centre of gravity of the four pistons, instead of being stationary, as would be the case if the connecting-rods were infinitely long, has a small harmonic motion of double frequency. It can therefore be balanced by reciprocating or rotating balance-weights, driven at twice the frequency of the main piston. Mr. Lanchester's ingenious method of doing this is to gear a pair of wheels carrying balance-weights to the main crank-shaft, which drives them at double its speed. As the wheels rotate in opposite directions, the components of the centrifugal forces of the weights always balance themselves in the plane through the axes of the wheels, but have a vertical component which balances the secondary inertia forces. Such a four-cylinder engine, though with its cranks in one plane, will have, as a whole, complete balance of mass, but the method involves calling into play two otherwise useless forces, with some addition to the weight and number of parts.

With four cylinders operating upon the two-stroke cycle, the cranks can, of course, be placed at right angles instead of at 180 deg., and then it is possible to secure complete balance of both primary and secondary forces, with exception of a couple produced by the secondary forces in the plane of the cylinders and crank-shaft, which tends to rock the engine in a fore-and-aft direction. This couple can usually be neglected in practical application. Engines with five and six cylinders in line, with either cycle, can, of course, be perfectly balanced as to the primary, and almost perfectly as to the secondary inertia forces.

To sum up, therefore, the only engine constructions in common use in which balance of mass is completely, or almost completely, secured by the neutralisation amongst themselves of the primary and secondary inertia forces, are the rotating engine, Fig. 3, above, the engine with five and with six cylinders in line, and the four-cylinder two-stroke engine with cranks at right angles. Of course also multiplications of these last three of the "V" or radial-type engine, in which the parts in each axial plane are balanced, are completely balanced as a whole. All these engines will be vibrationless when driven by an external force, provided the crank-case or framing is itself perfectly rigid. In practice it is not always possible, if the engine is very long, to obtain sufficient rigidity. With the light motor-car type, even if the

crank-case be sufficiently rigid, it is difficult when the crank-shaft is long to make it so stiff that the engine will not tend to vibrate relatively to its fly-wheel, whose mass-centre remains almost stationary.

Balance of Impulse.—Balance of mass is, however, insufficient by itself to produce a vibrationless engine, because it takes no account of the violently fluctuating pressures in the cylinders, and the consequent strains in the crank-shaft and engine framing. To secure freedom from vibration, it is necessary so to arrange the cylinders in relation to the crank-shaft that strains in the framing are either eliminated, or so balance each other as to have no tendency to shift the centre of gravity of the engine relatively to its crank-shaft and point of support.

If in Fig. 1 (page 103) the cylinders are arranged in line and fire simultaneously with exactly equal charges, there will be no tendency for the engine to move, except, of course, to rotate round the crank-shaft. The same result is obtained more simply in Fig. 2, which ensures equal pressures on the two pistons. Junkers obtains this equality of impulse, and, at the same time, a valveless two-stroke engine by his well-known arrangement, Fig. 6, but this, unfortunately, is unbalanced as to the secondary mass forces. The three cranks of each cylinder receive simultaneous impulses once only per revolution. The crank-shaft of the two-cylinder engine shown, therefore, receives virtually one impulse for every half-revolution. It will be seen, moreover, that in this, as in all single-acting engines, the pressures on the pistons during the compression and explosion strokes twist the crank-shaft first backwards and then forwards, producing a severe condition of stress, whilst the reaction of the crossheads on their guides also alternate in sign with each stroke.

If, however, a second pair of cylinders, each with a pair of pistons, be arranged tandem on the top of the first two, as shown in Fig. 7, each tandem line is then double-acting, and the cranks of the two sets can consequently be placed at right angles, when balance of impulse will be obtained with primary and secondary mass balance, except only as regards the rocking secondary couple in the principal plane of the engine. The torque transmitted to the crank-shaft, and the reactions of the crossheads on their guides, will then also be in one direction only. This arrangement, however, involves very great height and large number of parts, together with an expensive form of crank-shaft, and the same results are obtained more simply, and without these objections, in the author's arrangement, Fig. 8.

In this two open-ended cylinders, each with a pair of opposed pistons, are placed closely together side by side, and the upper piston of one cylinder is connected to the lower piston of the other by a pair of external oblique tie-rods, as shown, the piston A to the piston D, and the piston C to the piston B. An explosion between A and B drives B down and A up, drawing up D by the oblique rods, and giving two equal and opposite impulses to the two cranks. The pistons A and B, in separating, draw together the pistons C and D, compressing the charge between them. The engine operates upon the two-stroke cycle, the pistons at the ends of their stroke uncovering inlet and exhaust ports, as in the original Oschelhäuser arrangement.

The complete engine has two such pairs of cylinders, and a second pair of cranks at right angles to the first. The explosions in the four cylinders, acting upon the eight pistons, produce eight impulses per revolution, which are transmitted to the shaft in equal pairs. The vertical forces at all times balance each other, and, as in the Junkers engine, are not transmitted through the engine frame.

On referring to Fig. 9 it will be seen that the pistons of each pair are rigidly joined together and form one moving part. The centre of gravity of the pistons A and D is at the point q, and travels up and down on the line pq, whilst the centre of gravity of the other pair of connected pistons C and B is at the point p, and travels up and down on the same line. Thus the primary forces are perfectly balanced, and this is probably the only engine in which the centres of gravity of the balancing masses have exactly the same locus.

Secondary forces result from the fact that the common centre of gravity of all four pistons and their connecting-

THE BALANCING OF INTERNAL-COMBUSTION ENGINES.

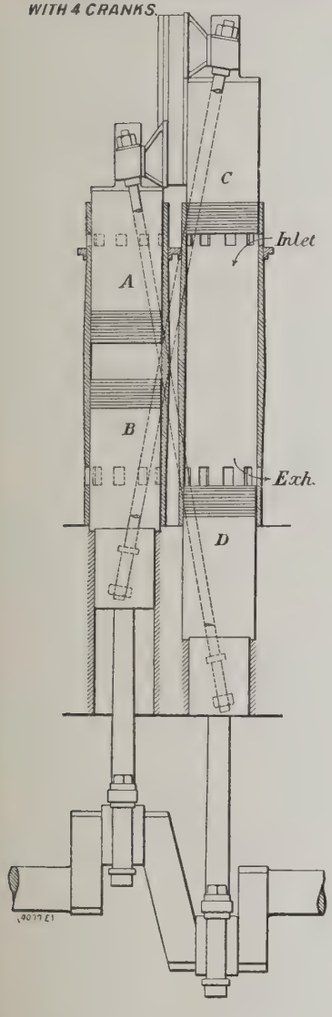

Fig. 9. COMPLETE PRIMARY BALANCE.

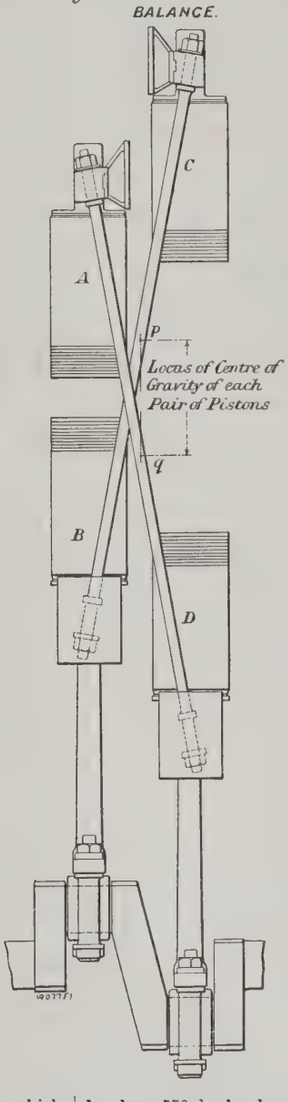

Fig. 10. WANT OF SECONDARY BALANCE WITH TWO CRANKS ONLY

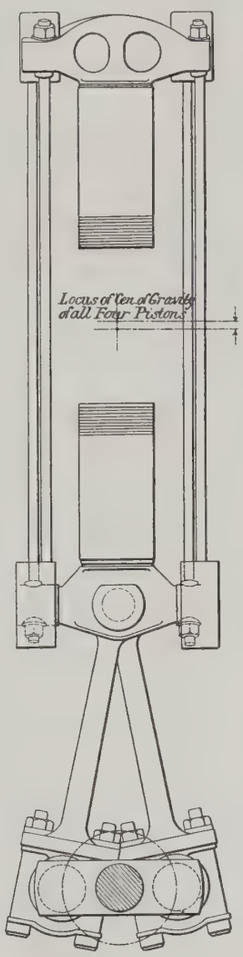


rods oscillates on the line $p q$ with an amplitude which, with a connecting-rod of the length of five cranks, is equal to $\frac{1}{10}$ of the stroke of each piston, Fig. 10. This force is, however, balanced by the corresponding force in the other pair of cylinders which oscillates in the opposite phase, and as the two pairs of cylinders are brought closely together, the secondary couple, which alone remains, is much smaller than in Junker's arrangement. With a six-cylinder engine of this type, even this secondary couple is entirely obliterated.

The Fullagar engine, therefore, obtains perfect or nearly perfect balance of mass, with complete balance of impulse. Excepting the small secondary couple above mentioned, no vertical forces are transmitted to the engine-frame. The only reactions on the frames are the horizontal thrusts of the crossheads on their guides, which are always in one direction, and are the unavoidable equivalent of the useful torque transmitted to the crank-shaft. In respect, therefore, of the combination of balance of mass, balance of impulse, and good turning effort, this engine is probably superior to any other of the reciprocating type hitherto built.

A 500-horse-power engine of this type has been in operation about a year. It has four cylinders of 12-in. (305 mm.) bore, and eight pistons with a common stroke of 18-in. (457 mm.), connected to a four-crank shaft. It develops 550 brake horse-power easily, and its weight, including a fly-wheel of 30 cwt. (1500 kg.), is under 21½ tons (21,000 kg.). The four pairs of connected pistons, weigh approximately 2 tons (2000 kg.), and, at normal speed of 250 revolutions per minute, when the pistons have a mean speed of 750 ft. per minute (3.8 m. per second), there is hardly any perceptible vibration. Even when the speed is increased to 300 revolutions per minute, giving a piston speed of 900 ft. per minute (4.57 m. per second), vibration is still very slight. At first sight it might be supposed that the oblique rods would involve considerable friction, but the angle of the rods is less than the maximum angle of the connecting-rods, and this friction is actually less than would be the case if each of the eight pistons had its own crank and connecting-rods. In the 500-horse-power engine above mentioned the mechanical efficiency, excluding the air and gas-pumps, is over 90 per cent.

The conditions of balance attained with the cross-connected construction of engine above mentioned is all that could be required for almost every application of internal-combustion engine; but there is still one unbalanced reaction of the engine itself—namely, the effort of each successive impulse to rotate the engine backwards round its crank-shaft, and there is also the gyrostatic effect of the fly-wheel or propeller which, in the peculiar case of aeroplane engines, it may be desirable also to eliminate.

To Mr. Lanchester belongs the credit of having produced the only engine extensively used in which, in addition to mass balance, torque balance was secured between the working parts of the engine itself. His well-known engine, which is shown in Fig. 11, was fitted to Lanchester cars about 1896. In this, it is sufficient to note, the primary forces were balanced by the balance-weights on the crank-shafts; the secondary forces of the pistons balance themselves, whilst balance of torque was secured by the oppositely-rotating fly-wheels. Balance of impulse was not obtained.

An engine which secures perfect balance of all forces is shown in Fig. 12. In this two opposed pistons in a single cylinder are connected to two oppositely-moving crank-shafts at opposite ends of the engine. The shafts need, of course, to be kept in phase by a lay-shaft and screw-gears or by a pitch-chain and spur-gears, though the connection has to perform no appreciable work under normal conditions. This arrangement has the further advantage that for aviation purposes two propellers can be driven directly. If of the same area as a single propeller, they will, of course, have a correspondingly less diameter, and for the same revolutions have 41 per cent. greater pitch ratio, a feature which will considerably increase their efficiency. If two such cylinders are placed side by side, and their connecting-rods coupled to opposite cranks, these rods will then balance each other. Such an engine will have absolutely perfect balance of all forces, mass, impulse, torque, and gyrostatic effect. By applying this two-shaft principle to the Fullagar cross-connected cylinder construction shown in Fig. 8 a two-stroke and double-acting engine is produced, in which each crank will receive two impulses per revolution. The engine then consists of two horizontal cylinders with four cross-connected pistons, one piston at either end being connected to separate crank-shafts at either end of the engine.

A still better arrangement for the same purpose is shown in Fig. 13, in which a pair of cylinders with cross-connected pistons is arranged in a plane at right angles to that of the shaft. Two such pairs of cylinders can be arranged side by side, with the cranks at right angles. Small balance-weights will then be needed to balance the connecting-rods, and four impulses will be transmitted to each crank-shaft per revolution. As the cylinders in either case work on the two-stroke cycle, an air-pump of some kind is required, and in Fig. 13 the two cross-heads of each upper cylinder are arranged to act as blowers, a method which has been found satisfactory.

These engines have absolutely perfect balance, and consequently exert no force whatever upon the fuselage on which they are mounted, except that due to their weight and to the useful thrust of the propellers when this is taken by the engine framing. All the metal in the stationary part of the engine is, moreover, usefully employed to support the engine and propellers, whilst its disposition renders it readily attached to and supported by the fuselage. Such an engine would appear to meet the requirements of aviation more completely than any arrangement yet devised, and, quite apart from the advantages of being "two-stroke" and double-acting, is, so far as the writer is aware, the only arrangement hitherto proposed which secures at the same time balance of both primary and secondary mass forces, balance of impulse, balance of torque, and balance of gyrostatic action.

THE PHYSICAL SOCIETY OF LONDON.

AT the meeting of the Physical Society of London, held on June 20, 1914, at the Cavendish Laboratory, Cambridge, Sir J. J. Thomson, O.M., F.R.S., President, in the chair, a paper entitled "*Production of Very Soft Röntgen Radiation by the Impact of Positive and Slow Cathode Rays*" was read by the President.

Röntgen and his pupils had always held that light waves were identical in nature with electrical waves produced by mechanical means; but there was a gap, on which very little work had been done, between the longest infra-red radiation and the shortest electrical wave that could be mechanically produced. He believed the investigation of this gap to be essential to the proper study of the constitution of the atom. The work already done on X rays had demonstrated the existence of two separate rings of electrons in the atom, one within the other. These rings were responsible for the K and L types of radiation respectively. The L radiation was so much softer than the K that if a third ring of electrons existed, the radiation from which was proportionately

softer than that of the L type, this radiation would fall well within the gap already mentioned.

In the first experiment described a special form of discharge-tube was employed. The positive rays passed through a tubular perforation in the cathode and impinged obliquely on a metal target. A photographic plate of the Schumann type was situated at the further end of a branch tube in such a position that no solid obstacle interposed between the target and the plate. When the discharge passed between the electrodes, the photographic plate was affected. The application of an intense transverse electrostatic field between two metal plates situated between the cathode and the target completely stopped the effect, showing that this was not due to stray radiation reflected from the target, since, while charged particles would be swept to one side, radiation would not be affected by the field. Hence the passage of positive particles from the cathode to the target was essential. On the other hand, a strong transverse electrostatic field in the branch-tube had no effect, showing that a radiation was passing between the target and the plate, which was not, therefore, merely affected by positive particles rebounding down the side-tube after impact on the target.

The properties of this radiation were intermediate between ordinary X rays and Schumann waves. They were susceptible to reflection by metal surfaces, and their penetrating power was very small. They were completely stopped by the finest collodion film obtainable.

It was shown that the quality of the radiation did not depend on the energy of the moving particles which gave rise to it, but on the velocity. Hence equally soft rays should be produced by cathode particles if these were travelling as slowly as the positive rays. A discharge-tube was constructed in which the cathode rays, leaving the cathode with the ordinary velocity, could be subjected to a retarding electrostatic field of variable strength before impinging on the target. In this way the velocity of impact could be varied over a large range, and radiations were obtained varying in quality from ordinary hard X rays to the so-called Schumann waves. It was hoped by the study of these radiations to be able to determine not only the number of rings of electrons within the atom, but the number of electrons in each ring.

Discussion.—Sir Oliver Lodge expressed the opinion that the work just described was of far-reaching importance, and he felt confident that the results warranted the anticipation that further work would confirm the explanation foreshadowed by the President. The full meaning of the experiments, and the way in which they enabled us to estimate the number of rings in the atom, was given to some extent in previous papers by the President and others. Eventually we would understand the argument more fully, and in this way the unravelling of the secret of the atom would be materially advanced.

A paper on "*The Homogeneity of Atmospheric Neon*" was read by Mr. F. W. Aston.

Dr. A. Russell proposed a vote of thanks to Sir Joseph and Lady Thomson for their kindness in taking so much trouble to ensure the success of the Society's visit to Cambridge. The vote was carried with enthusiasm.

At the meeting of the Society held on June 26, 1914 at the Imperial College of Science, Dr. A. Russell, Vice-President, in the chair. A paper entitled "*On Atmospheric Refraction and its Bearing on the Transmission of Electromagnetic Waves Round the Earth's Surface,*" was read by Professor J. A. Fleming.

In this paper the author considers the conditions under which true atmospheric refraction would be sufficient to carry a ray of light or electromagnetic radiation sent out horizontally from any point on the earth's surface round the earth parallel to its surface. It is now generally agreed that pure diffraction is insufficient to account for all the phenomena of long-distance wireless telegraphy, but that we have to postulate some action of the atmosphere which tends to curve the radiation round the earth. The theory of ionic refraction has been put forward, which is based on the theoretical conclusion that in ionised air the velocity of long electric waves is increased. We know as a matter of fact that the atmosphere decreases in density as we rise upwards, and this alone produces a decrease of refractive index and an increase in velocity.

The first part of the paper is concerned with the deduction of formulæ expressing this variation of density with heights taking into account as far as possible the known temperature variation with increase of height. It is shown that at a height of 100 km. the terrestrial atmosphere must consist substantially of hydrogen and helium. An expression is then obtained for the radius of curvature at any point of a ray of light sent out horizontally from the earth's surface, and it is shown that this radius at the starting point is given by the formula $\rho = \mu_0 / (98\ A\ q_0^2)$, where μ_0 and q_0 are the refractive index and density at the surface of the earth, and A is the Gladstone and Dale constant for the gas which forms the atmosphere. From known values for various gases it is shown that for air ρ is four times the earth's radius, for hydrogen 136 times, and for krypton equal to the earth's radius. Accordingly, if the terrestrial atmosphere consisted wholly of krypton, a ray sent out horizontally would be refracted round the earth, and in such an atmosphere wireless telegraphy to the Antipodes would be possible. The above formulæ are deduced in three ways. It is also shown that for the same atmospheric density and constant A this circular refraction would result if the earth were twice its present diameter.

The question of atmospheric composition is then considered in the light of what is known about the auroral spectrum. The suggestion is made that perhaps the non-valent gases neon and krypton are manufactured at great atmospheric heights by electric discharges occurring in the rarefied hydrogen atmosphere. Also that by their ease of ionisation they contribute to produce the ionised layer demanded by the theories of Heaviside and Eccles to account for the actual achievements of long-distance wireless telegraphy.

Finally, it is suggested that our earth is perhaps unique in being the only planet on which such long-distance radiotelegraphy is possible.

Discussion: Mr. Duddell considered it was very difficult to follow what was going on in long-distance transmission. One difficulty was that it seemed probable that the heavier gases were absent from the upper atmosphere, yet we had to assume their presence either to get the refraction effect or the Eccles effect.

Dr. C. Chree thought Professor Fleming's paper emphasised the importance of the field common to meteorology and wireless telegraphy. With regard to the relations between temperature, pressure and altitude in the atmosphere, aqueous vapour was an element which meteorologists had to take serious account of; its variability exercised a great influence on the results within 2 km. or 3 km. of the ground. With respect to the constitution of the upper atmosphere, more or less successful attempts had been made of late years to obtain samples by means of apparatus sent up by pilot balloons. On the theoretical side, there were papers more recent than the pioneer one by Sir James Dewar quoted by Dr. Fleming. In particular he would call attention to two papers by Wegener in the *Physikalische Zeitschrift* for 1911. A fundamental point was whether the auroral spectrum did or did not connote a gas different from all hitherto isolated at the earth's surface. Wegener thought it did, and believed the unknown gas thus indicated to be a very light one, which at great heights was even more important than hydrogen. The fact that Professor Störmer's recent photographic determination of auroral heights had in some cases supplied heights well over 300 km. was evidence that an atmosphere of some kind extended to a very great height. The fact emphasised by Dr. Fleming that wireless results by day and night differed markedly, certainly seemed to support strongly his contention that the upper atmosphere played a most important part in the phenomenon. A similar conclusion had been drawn in the case of the ordinary diurnal variation of the elements of terrestrial magnetism, where normally changes were much larger by day than by night, and much larger in summer than winter. It had been found, however, that while the difference between midsummer and midwinter existed in high altitudes, the difference between night and day was there much reduced, even at the equinoxes. Systematic wireless observations in the Arctic or Antarctic might throw a great deal of light upon the whole question.

Professor G. W. O. Howe congratulated Professor Fleming on his interesting and suggestive paper, and pointed out that although the upper atmosphere undoubtedly had a profound effect on the transmission of electro-magnetic waves over long distances, they were still uncertain to what extent long-distance radiotelegraphy would be possible without any assistance from the upper atmosphere. As successive mathematicians attacked the problem, errors were discovered in the previous work, and up to the present the effect of the correction seemed to have been in every case to increase the amount of energy diffracted around the globe.

Professor C. H. Lees mentioned that in the formula $(\mu - 1)/q = A$, the value assumed for μ was for sodium light, whereas the value required was for $\lambda = 500$ metres. Professor Marchant mentioned that in some work recently published it was shown that the difference between the carrying power of signals by night and by day was very much greater in summer than in winter. He asked within what limits of accuracy Gladstone and Dale's law held.

Professor Fleming, in reply, said that Dr. Chree's remarks were of importance, and the questions raised required to be cleared up. In reply to Dr. Lees, he said that for all gases the square root of the dielectric constant for steady voltage practically agreed with the refractive index for sodium light. It would be useful to have the known facts as to the nature of the atmosphere collected for the use of wireless investigators.

A paper on "*Atmospheric Electricity Observations made at Kew Observatory,*" by Mr. Gordon Dobson, was read by Dr. C. Chree.

The paper gives an account of experiments made to determine accuracy of the results obtained with the apparatus designed by Mr. C. T. R. Wilson for measuring the electric conductivity of the air, and the electric current passing from the air to the earth. Observations were made (1) using the standard instrument on a stand according to the usual practice and (2) using an experimental apparatus level with the ground, which was assumed to give correct results. It was found that it was necessary to apply a small correction to the results obtained with the standard apparatus when used in the ordinary way.

A comparison was also made of the electric conductivity of the air as measured by Mr. Wilson's apparatus and that designed by Professor Ebert. The results given by this latter apparatus appear to be too inaccurate to allow any satisfactory conclusions to be drawn.

Discussion.—Professor C. H. Lees said it was important to settle which was the better of the two methods. He thought the large Langevin ions were at the root of the trouble.

Dr. Chree said the large ions considerably affected the charge per unit volume, but he did not think they would affect the value of the earth-air current.

A paper on "*Thermal and Electrical Conductivities of Some of the Rarer Metals and Alloys*" was read by Mr. T. Barratt.

A new method of the "stationary temperature" type is employed for measuring the thermal conductivities of some of the rarer metals, including tantalum, molybdenum, rhodium, iridium, and tungsten, at air temperatures and at 100 deg. Cent.

It is shown that if a rod of metal is of length l, perimeter p, and cross-section q, then its thermal conductivity k is given by

$$k = \frac{H^2}{p q h\ V^2} \coth^2 a l,$$

where H is the heat given per second to one end of the rod, V the excess of temperature of this end over that of the enclosure, h the heat lost per second from 1 sq. cm. of surface when its excess of temperature over that of its surroundings is 1 deg. Cent., and $a = \sqrt{\frac{h\,p}{q\,k}}$.

If l is large, the equation reduces to the very simple form: $k = \sqrt{\frac{H^2}{p q h\ V^2}}$, this latter equation being employed in nearly every case.

Experimental details and the method of working out the results are given, and it is shown that the thermal conductivity of non-metals can also be determined in the same way.

Electrical conductivities of the same specimens have also been measured, and, for purposes of comparison with electronic theories, the values of $k/K\ T$ have been worked out, where k = thermal conductivity, K = electrical conductivity, and T = absolute temperature.

Discussion—Professor C. H. Lees thought the method extremely useful and simple. The accuracy obtained was quite sufficient to allow of verification of the ionic theories on which the author touched. His figures differed sufficiently from the theoretical value to show that the theory was only approximate in its present state.

Dr. Harker asked about the uniformity of temperature in the air space. The apparatus was horizontal, and if the heat supplied to the wire was very great, there were bound to be considerable irregularities of temperature in the chamber.

Mr. Barratt, in reply to Dr. Harker, said there was sometimes a very slow change of temperature of the air in the enclosure, but as the actual experiments, once conditions had become steady, took only a few minutes, the small change in temperature would not matter. Moreover, this change would affect both the hot end of the specimen and the cold one, so that the value of V, which was the object of the measurement, would not be altered. The same remark applied to the temperatures at the top and bottom of the water jacket. So long as the platinum thermometer was kept in the same place the measurement of V was unaffected.

A paper entitled "*Some Investigations on the Arc as a Generator of High-Frequency Oscillations,*" by Mr. F. Mercer, was read by Professor Marchant. This paper contains the results of a series of experiments on the copper-carbon arc when used as a generator of high-frequency oscillations. The copper electrode is water-cooled, and the whole enclosed in a cast-iron cylinder filled with hydrogen under pressure.

Preliminary experiments were carried out to determine the conditions which would give maximum steadiness of burning, and in the ensuing experiments these conditions were adhered to as rigidly as was possible.

The first experiments deal with the effect of varying the arc length, and also the arc current (by changing the resistance in series with the arc), on the magnitude and frequency of the shunt current The deduction is drawn that the effect on frequency arises from a change in the resistance of the arc.

The second experiment refers to the effect on the shunt current of altering the ratio of inductance to capacity. Keeping the latter constant and varying the former, a series of curves are obtained showing that for a given capacity there is a certain value of inductance giving maximum current in the shunt circuit.

Experiments were also made to determine the effect which the pressure of the hydrogen would have on the magnitude of the shunt current. This is dependent on the P.D. used. With small P.D 's the effect is negligible, at 1000 volts it is just appreciable, and at 2000 volts a marked increase is apparent. Beyond this it is impossible to obtain readings with any degree of accuracy, as the oscillations are very unsteady.

Discussion.—Professor Fleming mentioned that Mr. Bairstow had used an arc under pressure as a source of high-frequency oscillations over a year ago. He then described a more satisfactory method recently used by himself and Mr. Coursey. A number of carbons are fixed vertically to a metal plate which is suspended near the bottom of an iron vessel containing heavy oil. The carbons just project above the oil. Over each carbon tip is suspended a copper cylinder, the walls of which go down into the oil, and the thick top of which is perforated. Arcs are struck by lowering the cylinders until they make contact with the carbons, and then raising them with a screw. In this way very steady oscillations are obtained.

Mr. Duddell said that the Society was indebted to Dr. Marchant, who had come from Liverpool purposely to read Mr. Mercer's paper. Many of the observations mentioned in the paper were common knowledge to those who had worked with arcs. He would like, however, to call attention to the peculiar shape of the curves connecting the current in the shunt circuit and the frequency which the author had obtained, and in this connection he would like to ask the author whether the oscillations were of what are known as the first or the second type. If the latter were the case, it might be possible to explain the peaks on the curve, and that their position would probably depend on the relation between

the self-induction in the main circuit and the capacity in the shunt circuit.

Mr. E. H. Rayner asked what was the source of supply, and whether large amounts of inductance and resistance were used between the arc and source of power, as it might be that the character of the curves obtained might be modified if the "ballasting" in this part of the circuit were small. He also asked whether any attempt was made to load up the oscillating circuit with resistance to represent power radiated or otherwise employed. One would expect some modification in the results as compared with a "frictionless" oscillating system.

Professor Marchant, in reply, expressed his interest in Professor Fleming's generator. The author had found that when the power was too great the arc became unstable. He thought Mr. Duddell's explanation was probably correct, as the oscillations were of the second type. It was noticed that with a big capacity the peak was considerably less pronounced. There was a constant inductance in the circuit, and the current was reduced by adding resistance.

COLONIAL AND FOREIGN ENGINEERING PROJECTS.

WE give below a few data on several colonial and foreign engineering projects taken from the *Board of Trade Journal*. Further information concerning these projects can be obtained from the Commercial Intelligence Branch, Board of Trade, 73, Basinghall-street, London, E.C.

South Africa: H.M. Trade Commissioner for South Africa reports that a member of an engineering firm in South Africa, which already represents several United Kingdom machinery, &c., manufacturers, is now on his way to this country with a view especially to obtaining the agency of manufacturers of railway material. United Kingdom manufacturers of railway material may obtain the name and London address of the gentleman in question on application to the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, London, E.C., but they should address any further communications regarding the inquiry to H.M. Trade Commissioner for South Africa, P.O. Box 1346, Cape Town. H.M. Trade Commissioner has also forwarded the text of two Bills dealing with irrigation schemes, which have been laid before the Union Parliament. The first Bill proposes to authorise the Governor-General to make, out of public funds, a loan not exceeding 438,000*l.* for irrigation works in the Breede River Valley. The works comprise the construction of a diversion dam across the Breede River, and the construction of a canal crossing several rivers by inverted siphons, as well as all other works necessary to the scheme. The second Bill proposes to authorise the Government to proceed with the Hartebeestport Irrigation Scheme on the Crocodile River, in the Transvaal. A reservoir of 5,100,000,000 cub. ft. capacity is to be formed by the erection of a concrete and masonry dam, 160 ft. high, at Hartebeestport. H.M. Trade Commissioner reports that the East London Municipality, Cape Province, proposes to borrow a sum of over 12,000*l.*, of which amount 7814*l.* is to be utilised for the extension of the tramway system, covering duplication of the existing track and rearrangement of the overhead equipment, and 775*l.* for electric supply extensions, including high-tension feeder, static transformers, and switch-gear. H.M. Trade Commissioner further reports that the Fraserburg Municipality, Cape Province, is proposing to raise a loan of 3000*l.* for the installation of a local water-supply system.

Italy: The *Gazzetta Ufficiale* of July 2 announces that tenders are invited for the construction of the first section of a dyke in the roadstead of Brindisi, which, starting from the sand-bank of Punta Riso, in the Island of S. Andrea, goes towards the Island of Traverso. The total length is about 500 metres, and the estimated cost is put at 4,000,000 lire (about 160,000*l.*). Although this contract will doubtless be awarded to Italian firms, nevertheless the carrying out of the works may involve the purchase of materials outside Italy.

Bulgaria: The *Lieferungs-Anzeiger* (Vienna) of July 5 announces that the management of the Bulgarian State Railways will shortly be inviting tenders for the supply of 25 locomotives and 500 railway carriages, the estimated cost of which is 5,000,000 francs (200,000*l.*).

Norway: H.M. Consul at Christiania reports that, according to the local Press, it is proposed to build a new quay, about 377 yards long, at Arendal harbour at an estimated cost of 40,000*l.* It is also reported that plans are on foot for the construction at Bövaagen, on Karmöen Island, near Haugesund, of a dry dock capable of taking large merchant vessels and the ships of the Norwegian Navy.

Morocco: H.M. Chargé d'Affaires at Tangier reports that tenders are invited by the Moroccan Adjudications Commission for the construction of a section, 12 km. (about 7½ miles) in length, of the road from Rabat to Casablanca. The estimated value of the contract is 181,930 francs (7277*l.*), and a deposit of 3000 francs (120*l.*) is required to qualify any tender. Tenders, accompanied by certificates of competency, will be received by M. le Président de la Commission Générale des Adjudications et des Marchés, Dar-En-Niaba, Tangier, up to 11 a.m., on August 25. The contractor must elect domicile in the neighbourhood of the works. A copy of the *cahier des charges* may be seen, and copies of the form of tender to be used obtained, by contractors in the United Kingdom at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, London, E.C. With reference to the notice on page 763 of the *Board of Trade Journal* of March 26 last, relative to a call for tenders by the Moroccan Special Committee of Public Works for the construction of a lighthouse at El Hank, near Casablanca, H.M. Chargé d'Affaires at Tangier reports that the contract has been awarded, at a reduction of 19.2 per cent. on the estimated cost, to a French subject at Casablanca, whose name and address may be obtained by United Kingdom manufacturers of lighthouse material and equipment on application to the Commercial Intelligence Branch, as above. With reference to the notice on pages 121 and 122 of the *Board of Trade Journal* of April 16 last, relative to a call for tenders by the Moroccan Adjudications Commission for the construction of a section of the road from Salé to Kenitra, H.M. Chargé d'Affaires at Tangier reports that the contract has been awarded, at a reduction of 13.3 per cent. on the estimated cost, to an Italian firm at Casablanca, whose name and address may be obtained by United Kingdom exporters of road material on application to the Commercial Intelligence Branch, as above.

Costa Rica: With reference to the notice on page 120 of the *Board of Trade Journal* of January 16, 1913, relative to a call for tenders for a concession for the construction and working of a tramway from Alajuela to Grecia, H.M. Consul at San José reports that no further action has been taken with regard to tenders. The matter has, however, been discussed in Congress, and a Legislative Decree was issued on May 29 modifying the original decree. The principal modifications are that the line is to be extended from Grecia to the towns of Palmares and San Ramon; that the motive power shall be electricity, steam, or any other system of mechanical traction; and that the State will now guarantee interest at 6 per cent. per annum on the capital cost up to a total of 2,000,000 colons (about 191,300*l.*). The executive is authorised to spend the money needed to have the line surveyed, so that fresh tenders may be called for within eight months from the publication of the modifying decree—*i.e.*, before the end of January, 1915.

Portugal: The *Diario do Governo* of June 29 contains a law authorising the expenditure by the Government of a sum not exceeding 348,000 escudos (about 66,000*l.*) on the construction of a railway line from Evora to Ponte de Sor, including the construction of a bridge over the Raia. H.M. Consul at Oporto, in his report on the trade of that district in 1913, which will shortly be issued, states that it is reported that the specifications for the work of carrying out the improvements to Leixoes Harbour (see pages 36 and 37 of the *Board of Trade Journal* of July 3, 1913) are all but completed, and that the invitation for tenders will not long be delayed.

Spain: With reference to the notice on page 278 of the *Board of Trade Journal* of November 6, 1913, relative to the proposed construction of a broad-gauge railway from Saragossa to Caminreal, it now appears from the *Gaceta de Madrid* of July 3 that the Bill presented to the Cortes by the Ministerio de Fomento in this connection has now become law, and that the Government is authorised to announce a competition of plans for the construction of this line.

Italy: H.M. Consul at Milan reports the publication, in the *Sole* (Milan) of June 26, of the names of Italian firms with whom orders have been placed for the supply of rolling-stock required by the Italian State Railways. The contracts are for a total value of 56,302,000 lire (about 2,252,000*l.*), and include the supply of passenger-coaches, luggage-vans, and goods-wagons. The above-mentioned issue of the *Sole* may be consulted by United Kingdom manufacturers of accessories for railway rolling-stock at the Commercial Intelligence Branch of the Board of Trade, 73, Basinghall-street, London, E.C.

CATALOGUES.

Electricity in Coal-Mines.—We have received from the British Thomson-Houston Company, Limited, of Rugby, a pamphlet bearing the above title and illustrating examples of electric-power installations they have carried out in collieries. The illustrations, which are bright and clear, show examples of turbo-generators, switchboards, electric winding gears, electrically-driven screens, haulage gears, pumps, and other plant for work on the surface or underground. Nearly all the machinery and apparatus illustrated has been designed to comply with the latest Home Office regulations governing the use of electricity in mines. It is pointed out that recent mining legislation has rendered it imperative for those collieries desirous of maintaining their outputs under the new conditions to instal electrical machinery.

Pulley-Blocks and Runways.—Messrs. Herbert Morris, Limited, of Empress Works, Loughborough, have sent us a booklet giving full particulars of "H.M.B." spur-geared pulley-blocks, which they make with lifting capacities ranging from 2½ cwt. to 5 tons. The blocks are also made with geared or ungeared travelling carriages, which run on the bottom flange of an overhead steel joist, the load being moved horizontally either by pulling a chain or by simply pushing the load. Some examples of overhead runways, overhead travelling-cranes, and other lifting and transporting appliances, are illustrated. Another booklet from this firm deals with electric overhead runways and trolley-hoists, illustrating several examples. Full particulars are given of different types, having lifting capacities up to 15 tons; prices are stated in both booklets.

Lifts.—Messrs. R. Waygood and Co., Limited, of Falmouth-road, S.E., have sent us a copy of an eight-page pamphlet illustrating electric, hydraulic, and hand-power lifts for passengers and goods. The firm's patent "Electroil" lifts are also briefly dealt with. These lifts are intended for use where it would not be convenient to instal an ordinary electric lift, and where an hydraulic-power supply is not available. The lifts are operated by a direct-acting hydraulic ram supplied with oil under pressure from a special form of rotary pump driven by an electric motor. The power used is thus proportional to the load lifted, and another obvious advantage is that, since oil is the working fluid, all moving parts are kept thoroughly lubricated. Several of these direct-acting lifts have been installed for the purpose of lifting motor-cars, and a few suspended lifts are also being worked on the same system.

Oil-Engines.—From the Westinghouse Brake Company, Limited, of 82, York-road, King's Cross, N., we have received a copy of the latest edition of their catalogue of Cross patent vertical oil-engines. These engines were illustrated and described in our issue of January 27, 1911, on page 113, so that we need only remind our readers that they are of the four-cycle high-compression type, making use of the heat of compression to ignite the charge as it is sprayed into the combustion-chamber. It should also perhaps be mentioned that the special feature of the engine is that an annular pocket is formed in the cylinder walls near the upper end. This pocket, which is covered by the piston towards the end of the compression stroke, is uncovered early in the working stroke, so that the heated and compressed air in it mingles with the burning charge in the cylinder, and so completes the combustion. It is to this feature that the exceptional cleanliness claimed for the engine is ascribed. The engines are now built in sizes ranging from 7 to 120 horse-power for marine or stationary work, and the catalogue gives full particulars of the engines and also shows them in service for electric lighting, pumping, and other work. The firm's reversing-gear for marine work is also illustrated and described, and drawings and photographs of vessels on which Cross engines have been fitted for propulsion are reproduced.

Machine-Tools and Accessories.—From Messrs. Alfred Herbert, Limited, of Coventry, we have received sectional catalogues dealing, respectively, with combination-turret lathes, capstan lathes, drilling-machines, and small tools and accessories. The turret lathes dealt with are the firm's No. 3 combination type, for bar and chuck-work, fitted with single-pulley headstock, dial feed-motion, patent draw-in chuck, and many other special features, all of which are described in the catalogue. They have 8-in. centres, and can machine bars up to 32 in. long with one chucking. When the draw-in chuck is furnished, bars up to 2⅜ in. in diameter can be dealt with; but without it, bars up to 2¾ in. in diameter can be admitted through the spindle. The catalogue gives full particulars of the lathes, and of standard tool outfits for use with them. The section relating to drilling-machines gives particulars of sensitive drills with from one to four spindles fitted with ball-bearings. These bearings are put together in dust-proof housings, with a supply of grease which lasts almost indefinitely, so that oiling is neither necessary nor desirable. The list also includes bench drills, and radial drills with geared spindles, both types being also fitted with ball-bearings. The capstan-lathe section deals with two sizes having 5¼-in. and 6½-in. centres respectively. The smaller size, which is driven by a stepped-cone pulley, is capable of taking 1½-in. bars without the draw-in chuck, or 1¼-in. bars with the chuck, while the large size, which has a single-pulley headstock, can take 1⅝-in. and 2-in. bars with and without the chuck respectively. Full particulars of standard tool outfits for bar or chuck-work on these lathes will also be found. The one remaining catalogue section deals with Van Dorn portable electric drills, key-seating and oil-grooving tools, "Eternite" case-hardening composition, oil-filters, vices, pipe-wrenches, lathe and drill-chucks, stocks and dies, attachments for drilling-machines, milling-cutters, gauges, expanding mandrels, and many other small tools and accessories for the machine-shop; prices are stated for most of these articles.

Portable Electric and Pneumatic Tools.—From the Chicago Pneumatic Tool Company, Fisher Building, Chicago, Ill., U.S.A., we have received two bulletins dealing with Duntley portable electric tools. One of these bulletins gives particulars of drills and grinding-machines for use with direct current at 600 volts pressure, and therefore especially suitable for tramway and railway-track work, as they can be supplied with current from the trolley-wire or third rail. A portable tool for driving screw spikes, used in railway-track work, is also dealt with in this bulletin. The other bulletin gives full particulars of a special stand by means of which a portable electric drill can be converted into a sensitive bench drill. The stand is made in five sizes, to take standard Duntley drills, with capacities ranging from $\frac{5}{16}$ in. to ½ in. holes in metal. We have also received from this firm a number of publications dealing with pneumatic rock-drills of the percussion type, for mining, quarrying, tunnelling, &c. These include special drills for plug and feather work, stoping-drills, and sinking-drills for large deep holes, as well as drills for ordinary service. In these drills the valve consists of a hollow steel ball, the travel of which is only about ⅛ in. Its movement is thus very rapid, so that the drill delivers a very large number of strokes per minute. A dust-allaying device for use with these drills is also illustrated and described. It consists of an air-jet which draws up water from a bucket near the drill and delivers it in the form of a spray round the mouth of the hole. One other publication still remains to be mentioned. This is a bulletin devoted to rotary drills, operated either by pneumatic or electric power, and intended for use in coal-mines. They are capable of boring a 2-in. hole 6 ft. deep in from one to three minutes, according to the hardness of the coal. All these bulletins, which are well printed and clearly illustrated, give dimensions, prices, and all other necessary particulars of the appliances they relate to. The London address of the company is the Consolidated Pneumatic Tool Company, Limited, 9, Bridge-street, Westminster, S.W.

"ENGINEERING" ILLUSTRATED PATENT RECORD.

SELECTED ABSTRACTS OF RECENT PUBLISHED SPECIFICATIONS UNDER THE ACT OF 1907.

The number of views given in the Specification Drawings is stated in each case; where none is mentioned the Specification is not illustrated.

Where inventions are communicated from abroad, the Names, &c., of the Communicators are given in italics.

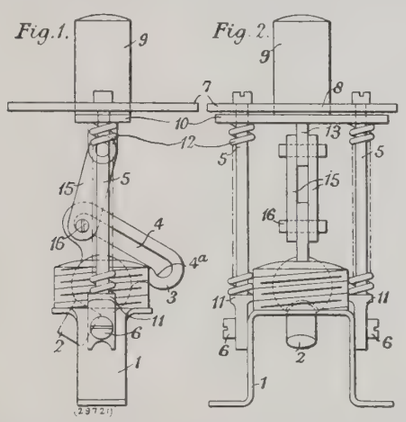
Copies of Specifications may be obtained at the Patent Office, Sales Branch, 25, Southampton Buildings, Chancery-lane, W.C., at the uniform price of 8d.

The date of the advertisement of the acceptance of a Complete Specification is, in each case, given after the abstract, unless the Patent has been sealed, when the date of sealing is given.

Any person may, at any time within two months from the date of the advertisement of the acceptance of a Complete Specification, give notice at the Patent Office of opposition to the grant of a Patent on any of the grounds mentioned in the Act.

ELECTRICAL APPARATUS.

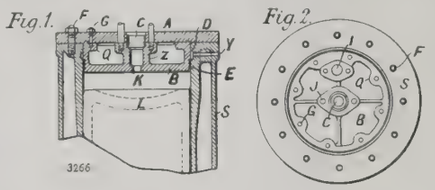
29,721/13. A. P. Lundberg, G. C. Lundberg, P. A. Lundberg, and G. Pegg, London. Electrical Switches. [2 *Figs.*] *December* 24, 1913.—This invention has reference to electrical switches, and has relation to means or arrangements whereby the contact-making and breaking member of the switch may be actuated to or from its "on" or "off" position by the depression of a button, one, or the first depression of the button effecting the firstly-mentioned movement, and another, or the next depression effecting the secondly-mentioned movement. It has already been proposed to actuate switches by the depression of a button through links and a pin and slot connection in such wise that when pressure is applied to the button, such pressure acts directly on the contact-making member, which is caused to move in one direction, the button, links and pin, when the pressure on the button is removed, being caused by a spring to assume positions which, when pressure is again applied to the button will cause the contact-making member to move in an opposite direction. In conjunction with such mechanism it has also been proposed to mount a pair of arms on opposite sides of the switch member, and to connect their free ends, said arms serving as guides for the push-button, and carrying springs which serve to return the push-button to its normal position. The object of this invention is to adapt the push-button actuating mechanism referred to to a tumbler switch of the type in which the actuating or tumbler-lever has a knob or dolly at its free or outer end, and a ball or boss intermediate of its ends, the ball or boss being pivotally mounted in a recess or opening formed in a bridge member or piece, so that the inner end of the lever which end acts upon the contact-making members, is between the two legs of the bridge member. The adaptation consists in dispensing with the knob or dolly on the free end of the actuating-lever, substituting therefor a slotted cross member to form one part of the pin and slot connection before referred to, and mounting the two arms connected at their free ends, which serve as guides for the push-button and carry the springs for returning the push-button to its normal position, at opposite sides of the bridge piece.



1 is the usual bridge member or piece of an electrical tumbler-switch, having levers and members movable as described, in which the actuating-lever 2 is pivotally mounted. In carrying out this invention, the actuating-lever, instead of being provided with a knob or dolly, as is usual, is provided with a cross-member or piece 3, and this cross-member 3 is slotted parallel with its length. The dimensions of the slot 4 at its ends are made slightly greater than the dimensions of the main portion of the slot. 5, 5 are arms mounted at their one ends on the opposite sides of the bridge member 1, and secured thereto by screws 6 or the like. The arms 5, 5 extend upwardly in relation to the bridge member 1, are parallel the one with the other, and at their upper ends are secured to a plate 7, centrally of which is a hole 8. 9 is the press-button. This press-button is mounted in the hole 8 in the plate 7, and is movable in relation thereto. The button 9 is carried by a plate 10, and the plate 10 is mounted on and movable in relation to the arms 5, 5. Between the under face of the plate 10 and a shoulder or abutment 11, formed or provided on each of the arms 5, 5 near the lower ends thereof, is a spring 12. These springs 12 maintain the plate 10 at the upper ends of the arms 5, 5. When pressure is applied to the button 9, the plate 10 is moved in relation to the arms 5, 5 and against the action of the springs 12, 12. The lower end of the button 9 is provided with an extension 13. This extension 13 extends through the plate 10, and below the plate 10 is connected as by a pin with the one ends of a pair of links 15, the other ends of which are connected together by a pin 16 that also engages the slot 4. The lengths of the cross-member 3 and the slot 4 therein are such that when the contact-making and breaking member is in the "on" or "off" position, and the pin 16 is at one or other end of the slot 4, the links 15 are inclined with relation to the arms 5, 5. When the pin 16 is at one or other end of the slot 4, it is in engagement with one of the depressions 4*a*, and such depressions prevent slipping or movement of the pin 16 in relation to the slot 4, while pressure is being applied to the button 9. (*Sealed June* 25, 1914.)

GAS-ENGINES, PRODUCERS, HOLDERS, &c.

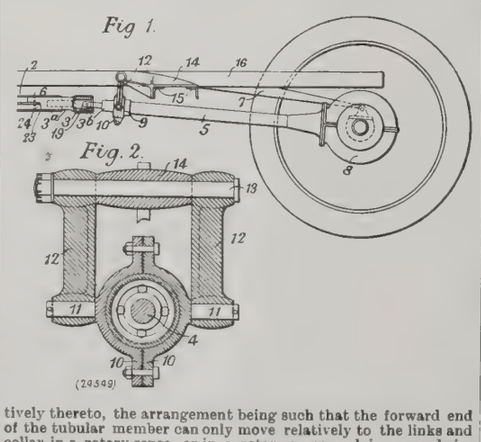
3266/14. Scott's Shipbuilding and Engineering Company, Limited, and J. Richardson, Greenock. Internal-Combustion Engines. [7 *Figs.*] February 7, 1914.—This invention relates to internal-combustion engines—for example, to engines of the Diesel type—working preferably on the two-stroke-cycle, the scavenging system of which is such as to permit of the reduction of the number of valves fitted to the cylinder-head to a minimum. The object of the invention is to provide in such engines an improved form of cylinder-head constructed in two parts—one of which is formed as a plate of sufficient thickness to take the load of the explosion, and the other of which is formed as an inwardly-dished element fitted into the cylinder and serving in conjunction with the plate to carry the valves, the space between the parts forming a cooling-water space. Referring to the drawings: S indicates the cylinder, K the combustion space, and L the main piston of an internal-combustion engine embodying the invention. The piston may contact directly with the inner wall of the cylinder, as shown, or the cylinder S may be fitted with a separate liner. Within the cylinder S is loosely fitted a dished element B, affording, in con-



junction with the substantially flat cylindrical cover-plate A of forged steel secured to the cylinder by studs F, a closed water-cooling space of shallow dimensions. The dished element is preferably fitted with packing-rings E, preferably of copper or bronze, and shaped after the manner of piston-rings to ensure tightness. Any leakage which may pass the rings E, and the wall of the cylinder or liner, is trapped in an annular space D formed in the cylinder wall or in the liner, and is led off by a pipe Y. The dished element B is secured to the plate A by means of studs G, and is formed with an inwardly-projecting flange Q spigoted into the cover-plate A, as shown, or with an outwardly-projecting flange fitting into the cylinder wall or into the liner wall, so that these parts form a rigid unit. The fuel-injection valve C may be carried by a boss Z formed integral with, and, for instance, disposed centrally of, the dished element B. An additional valve I, or valves, may be fitted adjacent to the valve C, as shown in the drawings. (*Accepted April* 15, 1914.)

MOTOR ROAD VEHICLES.

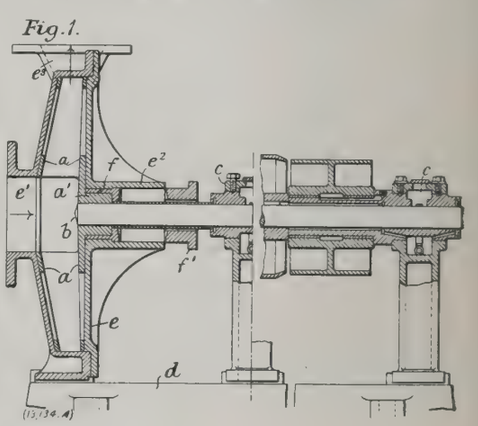
24,549/13. A. M. Arter, E. Arter, and Marshall Arter, Limited, London. Motor-Propelled Road Vehicles. [2 *Figs.*] October 29, 1913.—This invention has relation to motor-propelled road vehicles, and has reference, in particular, but not exclusively, to a motor-propelled road vehicle having a back axle with combined differential and change-speed gearing, such as is described in the Specification of Letters Patent No. 28,327, dated December 16, 1911, and a propelling member or members intermediate the prime mover and the change-speed gearing and differential gearing, such as described in the Specification of Letters Patent No. 2818, dated February 3, 1912. It has been proposed to enclose the propelling member within a tubular member connected at one end with the casing of the differential gearing and/or back axle, and connected at its other end to the chassis by means of a connecting-rod, one point of articulation of which was constituted by a ball-and-socket joint fixed rigidly to a transverse member, while the other point of articulation was constituted by the front end of the tubular member itself ending in a ball-and-socket joint. This construction enables the vertical reactions which are transmitted to the forward end of the tubular member to be resisted, and permits angular and longitudinal movements thereof. Now, in the improvements in accordance with this invention, the tubular member is mounted at its forward end in a collar carried by, and between, the one ends of a pair of links, mounted at their other ends on the vehicle chassis in such wise as to be incapable of lateral movement rela-

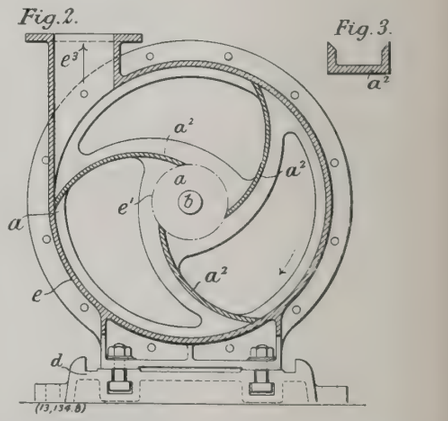


tively thereto, the arrangement being such that the forward end of the tubular member can only move relatively to the links and collar in a rotary sense, or in a rotary sense and in an endwise direction. In carrying out this invention, the drive is transmitted from the engine to the load through the agency of a propelling member 2, as described in Specification No. 2818, of 1912. The propelling member 2 is driven by the engine through a clutch. The one member of the clutch is provided with a boss, on which are shoulders, between which is mounted a collar connected with the clutch-pedal. When the clutch-pedal is actuated the clutch member is moved out of contact with the other clutch member. The two clutch members are normally maintained in engagement by a spring, as well understood. The boss of the first-mentioned clutch member is provided with an extension having a curved face, and is also provided with a slot, in which one end of the propelling member 2 is secured. The other end of the propelling member 2 is mounted and secured in a slot 23 formed in the end of an extension of prolongation 24 of the member 3*a* of the universal joint 3. The propelling member 2 is secured in the slot 23 by a bolt or pin, which serves to aid in the securing of a tube 6. This tube, which may be secured to the extension 24 by other bolts or pins, is of a length to extend the full length of the propelling member 2, and its other end is in contact with the extension of the boss of the firstly-mentioned clutch member, but is not secured thereto in any way. The member 3*a* of the universal joint is slotted, and in the slot work the blocks 19, to which is connected pivotally the other member 3*b* of the universal joint to which the propelling member 4 is connected. The propelling member 2 and the member 3*a* of the universal joint are always maintained in the same line, and when declutching takes place, the propelling member 2 and universal joint member 3*a* move relatively to the universal joint member 3*b*. The universal joint member 3*b* is connected to the one end of the propelling member 4, the other end of which is connected through gearing with the load. In the example, the rearward end of the propelling member 4 carries the small bevel-wheel that gears with the crown wheel and differential gearing of the back axle. The back axle and gearing is, as usual, enclosed within a casing 8, and to this casing is rigidly attached the one end of a tube 5. The propelling member 4 is enclosed within the tube 5. The tube 5 forms the torque member, and its other and forward end, which extends as far forward as the universal joint 3, is carried by links 12. The forward end of the torque member 5 has a sleeve 9 fixed thereto, and this sleeve 9 is embraced at or near its outer end by a two-part collar 10. In the construction illustrated, the collar and sleeve are such that endwise movement of the sleeve in relation to the collar is not possible. The collar 10 has diametrically-arranged bearing-pins 11, and on these pins are mounted the one ends of the links 12. The other ends of the links 12 are mounted on a pin or spindle 13 carried by a bracket 14 mounted on and carried by cross-bearers 15 of the chassis 16. The links 12 can thus only have a to-and-fro motion in the longitudinal plane of the chassis. The lengths of the links 12 and the position of the spindle 13 are so chosen that the propelling member 2 and tube 6 are horizontal, or nearly so, and the torque member 5 and links 12 at right angles, or nearly so, to one another. (*Sealed June* 25, 1914.)

PUMPS.

13,134/13. Bertrams, Limited, Edinburgh, and G. Robertson, Aberdeen. Centrifugal Pumps. [3 *Figs.*] June 6, 1913.—This invention has reference to centrifugal pumps of the kind adapted to allow for the impeller spindle and bearings being removed without disturbing the suction and discharge-pipes, and it consists of an improved construction of this class of pump, specially designed for paper-mill work and for dealing with thick pulp, one of the features of the pump being an impeller adapted to give full-way passages for the liquid to be pumped, and formed with opening in its sides, and having its blades of straight or curved shape in cross-section, and made integral with such sides, those edges of the impeller or blades contacting with the edges being bevelled. In a centrifugal pump, according to this invention, the impeller is adapted to give full way passages for the liquid to be pumped, and is formed with openings in its sides and with blades of straight or curved shape in cross-section, integral with such sides, those edges of the impeller or blades contacting with the casing being bevelled. In carrying out the invention, the impeller *a*, which is provided with a laterally extending boss a^1, is mounted upon the end of a





shaft *b* supported in pedestal bearings *c*, *c* upon a bed-plate *d*. The bed-plate also supports the pump casing *e* having central inlet opening e^1 on one side and an outwardly-extending tubular boss e^2 on its opposite side. Into this latter the boss a^1 of the impeller projects to lie within or against a flanged neck-ring or bush *f* held in position by the packing gland f^1. At the top of the casing is the discharge outlet e^3 which is preferably of rectangular formation on the inside and circular on the outside, the cross-sectional area of the outlet at any point, however, being not less than the area of the inlet opening e^1. The impeller *a*, the sides of which are of open-work formation, as shown in Fig. 2, is formed or provided with curved blades a^2 which extend from the inner periphery or wall of the casing towards the centre, their inner ends or edges terminating at distances from the centre equal to the radius of the inlet opening. The blades or vanes a^2 produce channels or troughs of the section, shown at Fig. 3, the vertical edges being of sharpened formation or bevelled, and thus serving to clean the side of the casing *e* and prevent the pulp jamming between the impeller and casing (*Accepted April* 29, 1914.)

LITERATURE.

The Scientific Determination of the Merits of Automobiles. Reports I. to IX. of the Laboratory for Motor-Cars at the Royal Technical University, Berlin-Charlottenburg. By Dr. A. RIEDLER. London: The General Oil Publishing Company, Limited, 6, Broad-street Place. [Price 21s. net.]

WHILE there has been a great deal of money spent on various trials of motor-cars since the start of the industry, it is certainly a fact that it has produced far less definite scientific information for the expenditure than in the case of any other trade. A large amount has, for instance, been spent in racing, with practically no scientific result at all, for it is impossible in the case of a race to separate the influence of various factors on the result, and one of the most important of them—namely, the skill of the driver, has no bearing whatever on the subject of the merits of the car. The volume now before us is therefore exceedingly welcome, giving, as it does, very definite information as to the performance of several cars. The greater part of the book consists of a description of the testing-plant and a simple statement of the results obtained with it. Certain conclusions are drawn from these results.

The method of testing adopted is to place the car on a test-bed with its wheels resting on rollers situated below the floor, these rollers being connected to dynamos, which can, if desired, be also used as motors. The shaft on which the rollers are mounted also carries two friction brakes. The power at the road-wheels can therefore be measured either by the dynamos or the brakes. Further, arrangements are made for measuring the tractive force of the vehicle under test, the front wheels being carried on a roller-bed, and the tractive force taken at the back axle. This checks the accuracy of the brake measurements. Means are provided for measuring separately the various items of both power and loss, and in all cases these measurements are taken as nearly as possible in actual running conditions. For instance, to get the brake horse-power of the motor separately it is not dismounted from the chassis and placed on a test-bed, but is tested mounted on the chassis, where all parts will be subject to the same vibration effects, as far as these depend on the motor, as will be the case in actual practice. It is considered that this gives more accurate results than mounting the motor on a rigid test-bench, as in the latter case various parts are subject to much less vibration. From these tests a balance-sheet is made of the total available energy in the fuel and how it is expended. These measurements are taken for the various speeds with which the car is provided and at different revolutions of the engines, and curves drawn of the available tractive force. Curves are also drawn of the various items of resistance. From these the speed of the car can be estimated on the flat and also the margin of power available for hill-climbing at any given speed. The only item not actually measured in this is the air-resistance; but this is calculated, and it is stated that the actual speed of the cars tried corresponds so nearly to the calculated speeds as to show that the assumption of air-resistance is sufficiently accurate for practical purposes. On hills, and at moderate speeds, the air-resistance is not a very large proportion of the available power of the car, and therefore will not materially affect the actual performance.

The following cars were tested:—

30-horse-power Renault touring-car.
100-horse-power Benz racing-car.
70-horse-power Adler touring-car.
Mercédès electromobile.
35-horse-power Büssing military transport-wagon.
40-horse-power English Daimler-Knight car.

Tests were also made of a Mercédès-Knight engine, and comparisons are made between the Knight and poppet-valve systems.

As an example of the results obtained we may take the trials of the 30-horse-power Renault, premising that this is a very old type, built in 1905, and therefore does not in any way represent Renault's present practice. A series of curves are given of the available motor power at various speeds, there being a different curve for each of the three gears. Below these are curves each showing the result of deducting one of the various losses—*e.g.*, transmission, the rolling resistance, &c. The lowest of these, therefore, gives the power available for air-resistance and hill-climbing. The point at which this curve crosses one plotted to represent the air-resistance is therefore the speed the car will attain on a flat road, and at any speed below this the margin of power for hill-climbing can be ascertained by measuring the distance between the two curves. The curves cross at 69 km. (43¾ miles) per hour.

At a speed of 60 km. (37½ miles) per hour the balance-sheet of the available energy of the fuel is as follows:—

	Per Cent.
Cooling water	35.8
Exhaust gases and radiation	35.6
Exhaust piping	1.0
Silencer	1.2
Friction of motor	5.6
Driving-gear	2.9
Back tyres	3.7
Front tyres	1.1
Friction and air resistance of front wheels	0.6
Air resistance of car	7.1

The balance is available for gradients or acceleration. At the same speed the percentages of losses of the available power of the engine without silencer are as follows:—

	Per Cent.
Exhaust-piping	4 5
Silencer	5.2
Transmission gear	12.7
Friction and air-resistance of front wheels	2.6
Front tyres	4.8
Back tyres	16.2
Air-resistance of car	31.0

The balance of 23 per cent. of the power of the engine is available for gradients and acceleration.

This car had a motor with four cylinders, 100 mm. by 140 mm. (4 in. by 5½ in.), having valves 36 mm. diameter by 6½ mm. lift ($1\frac{7}{16}$ in. by ¼ in.). The compression ratio (total volume ÷ compression space) was 4.02. Three speeds were provided of a ratio, engine to back wheels, of 10.8, 5.83, and 3.14, the latter being direct. The tyres were 875 mm. by 105 mm., the external diameters of the wheels, as actually measured, averaging about 895 mm.

As a contrast to this, we may take the 70-horse-power Adler, which has cylinders the same diameter as the Renault, but 150 mm. ($5\frac{7}{8}$ in.) stroke. The valves are, however, much larger—namely, 56 mm. (2¼ in.), with a lift of 9 mm. (⅜ in.), and the compression ratio is 4.76. The top speed has a ratio of 2.895, and the back wheels have tyres nominally 820 mm. by 120 mm., but which actually measured about 816 mm. diameter.

Curves of performance similar to those of the Renault car are given, and show that a speed of 114 km. (71 miles) an hour should be obtained on the flat. The balance-sheet of the effective power of the motor is as follows:—

	Per Cent.
Transmission losses	16 0
Friction and air-resistance of front wheels	4.7
Front tyres	4.6
Back tyres	26.7
Air-resistance of car	48.0

In comparing these results with those of the Renault, it is to be observed that the speed is nearly twice as great, and that the effective power is taken for the motor with silencer, whereas in the case of the Renault the loss of power from silencing is included in the losses. It is stated, however, that the exhaust was only "slightly silenced," so the power might have been materially reduced by a really effective silencer. The weight of this car, with a four-seater racing body, including tools and 9 gallons of petrol, was 21 cwt.; and with three passengers 25½ cwt.

Want of space forbids our giving further extracts from the details of the tests, which cover the greater part of 300 pages, all of which are of interest, and therefore we are compelled to be content with a few general observations.

The two motors compared above represent two different types—namely, the one with comparatively small valves and built for quietness, and the one with large valves built for power. The Adler, of course, gives over twice the power of the Renault, the powers being almost exactly proportionate to the area at the lip of the valves. A great part of this increase in power is, however, solely due to the fact that the Adler engine will run at much higher revolutions. The cars are, however, geared to much about the same speed at the same revolutions, and therefore this extra engine speed of the Adler is only useful at very high road speeds. Thus, at 50 km. an hour (32 miles), which is much more like the usual travelling speed of the ordinary motorist than the racing speeds mentioned, the Adler engine is running at about 1000 revolutions, the Renault at 950. Under these circumstances the Adler will give about 42 horse-power, and the Renault 22 horse-power. Part of the difference is, no doubt, due to the better silencing of the Renault, and part to the lower revolutions and shorter stroke; but it seems evident that the larger valves have a distinct effect even at such low revolutions. Whether the rise in power is worth the disadvantages of the large valves is, of course, a matter of opinion. The Renault being of an old pattern, it is, however, reasonable to expect that a more modern type would give considerably greater power without undue noise.

Of the general conclusions drawn, one of the most interesting points is the loss of power in the transmission and the road-wheels. Various estimates of the loss in transmission have been made, some of them higher, some lower, than that shown; but it has not been generally thought that the loss in rolling resistance of the back wheels was very great. The actual losses between the engine and the rims of the back wheels at 60 km. (37 miles) per hour were: English Daimler and Benz, 11 per cent. of the brake horse-power of the motor; Renault, 12.7 per cent.; Adler, 12.8 per cent. At 16 km. (10 miles) the Bussing lorry had a loss of 18 per cent. It is noticeable that the loss of power in the gearing rose with the engine speed, the loss being 16 and 16½ per cent. in the Adler and Benz respectively at full motor speed of something over 2000 revolutions.

It is curious that although the top speed is direct in all four cars tested, the loss by gearing does not seem to materially increase on the lower speeds. It would have been expected that the loss would have been much greater on the lower speeds, as there are two extra pairs of gear-wheels for the power to pass through. In the Bussing lorry the drive on all speeds is through spur-gear, bevel-gear, and chains, the requisite reduction not being obtainable on one drive, and this accounts for the greater loss than in the cars. It appears likely that the loss through the fluid friction of the oil in the gear-box is considerable, and the fact that many of the wheels are revolving more slowly on the lower speeds may be the reason for the relatively small loss in them. This points to the advantage of using thin oil in the gear-box.

Another point of interest is the great loss through the rolling resistance of the back tyres. It will be seen that in both the Renault and Adler the loss through rolling resistance of the wheels is greater than that through friction in transmission; and, further, that although the front and back wheels carry nearly the same weight, the loss is far greater in the back wheels than in the front. The same effect is observed in the Bussing lorry, and is shown to be due to the internal friction of the tyre under the deformation produced by the driving stress. Diagrams are given showing the loss when running light and when transmitting the engine power, and it is shown that on the lower speeds, when the driving stress gets very high, the rolling resistance, when transmitting the power, may be ten times that of the wheels running light. This very well explains the greatly increased wear of driving tyres as compared with those carrying load only.

Whether the conditions of rolling on a drum accurately reproduce rolling on a flat road is not stated, but there appears no reason why any difference should affect the relative resistances of the front and back wheels. This difference therefore raises a point which should bear further investigation.

A rather interesting point is the actual weight of some of the cars tried. As mentioned, the 70-horse-power Adler only weighed 21 cwt. with a four-seated body. The racing 100-horse-power Benz, having four cylinders 115 mm. by 175 mm. (4½ in. by $6\frac{7}{8}$ in.), weighed 26½ cwt. with tools and 9 gallons of petrol. On the other hand, the Renault weighed 31 cwt., and the Daimler, with cylinders 101.6 mm. by 129 mm. (4 in. by 5 in.), weighed 28 cwt., of which the chassis weighed 22 cwt. It is well known that the ordinary modern four-seater car, with cylinders, say, 90 mm. by 120 mm. (3½ in. by 4¾ in.), generally weighs well over 24 cwt. While it is doubtless impossible to get the weight as low as in a racing-car and have a comfortable body, it appears that there should be considerable margin for reduction.

At the end of the book a summary is given of the conclusions come to as a result of the trials. A great deal is said about the advantages of high-

speed motors and the possibility of reducing weights by the adoption of high speeds. The author does not appear to have grasped the fact that the greater part of the weight of a motor does not consist in the cylinder barrels, but in the crank-shaft, crank-case, valves, valve-pockets, &c., and that above a certain speed these have to be made very much heavier than in the moderate-speed engine. Curiously, he quotes the Benz as a proof of his contention that weight can be reduced by excessive engine speed, whereas the fact is that the Benz aero-engine, which is obviously made as light as the builders can make it consistent with its not breaking down, runs at a very moderate speed. He states that the advent of the high-speed engine was delayed by the motor-cycle type having failed, but that at present the high-speed engine is becoming universal for car work. If this is the case, however, it is only so as regards Germany, whose contribution to the motor-cars of the world has not been a very large proportion. The facts are that the early French motor-cycle engines had all the essentials of the modern high-speed engine, and performed exceedingly well, in fact, all high-speed engines are, more or less, copies of them. The extreme high-speed car-engine has, however, only been adopted, even in Europe, where an arbitrary system of rating has favoured it. All the larger and more expensive European cars are fitted with such gear ratios that the engines are run at very moderate revolutions at ordinary touring road speeds, while the American cars of all kinds have moderate-speed engines, and the sale of these is extending rapidly all over the world.

An interesting point is that in the trial of the motor-lorry a trailer was also tested, and it was found that its rolling resistance was far greater than that of the lorry. It is suggested that there is room for a good deal of improvement in trailers. A considerable amount of space is devoted to a consideration of the requirements of the lorry, and how they can be met, all of which is of very great interest.

Mention is made in this connection of the advantages of the worm-drive as a means of simplifying the transmission gear. In the Bussing lorry three successive reductions were made to get the desired gear ratio. With a worm-drive, this could be done in one. The author, however, appears not to be well acquainted with modern worm-drives. Thus he states that the loss in the worm is great, and also that it is irreversible. In actual test, however, the efficiency of the transmission gear of the English Daimler with worm-drive is given as varying from a minimum of 84 per cent. on the lowest speed to a maximum of 90 per cent. on the top. That is to say its efficiency is given as being as high as that of the other gears tested. With regard to the question of reversibility, this depends solely on the angle of the worm, and all worm-drives for vehicles are made of such an angle that the wheel will drive the worm perfectly well. The worm is spoken of as if it were a quite untried device for commercial work, but it has been used for this purpose in England for six years or more.

While there are naturally points open to criticism in a book dealing with such a large range, there is no doubt as to its great value. The contents bear witness to an enormous amount of work, and when we state that it consists of over 330 pages, with 227 illustrations, and is, as a whole, very concisely written, it will be seen that it is impossible here to deal with even a small fraction of it, and it should certainly be studied by all those in the least interested in scientific motor construction.

Compressed-Air Practice. By FRANK RICHARDS. New York: McGraw-Hill Book Company, Inc. [Price 12s. 6d. net.]

THE ever-increasing spheres of usefulness of compressed-air appliances, and the large compressed-air and high-pressure gas schemes which have been rendered practicable by the increased efficiency, capacity, and reliability of the modern compressor, of both reciprocating and centrifugal or turbine types, render the volume under review of considerable interest.

The author first makes a few observations as to the functions of air in Nature, and then deals with definitions and general information—*e.g.*, conversion tables of weight, temperature and pressure, and tables of weight and volume of air at different altitudes. The causes of loss of energy between compression and expansion are explained by reference to adiabatic and isothermal curves. Tables and graphic charts are given for the various computations involved in compressed-air calculations. He then proceeds to deal with the uses of the indicator, and explains the proper interpretation of indicator diagrams and their bearing on the proportioning of the cylinders of two and three-stage compressors. The illustrations include cards indicated on old machines, and their faults are enlarged upon.

Continuing, the various devices for compressor regulation are explained, and their relative advantages discussed, special attention being given to "clearance controllers." The author then mentions how the big contracting companies who excavated the underground subways in New York were amply repaid by the adoption of every refinement on the steam and air sides of their compressor plants, and that, notwithstanding the fact that these machines which proved so efficient were available for the work of excavating further tunnels shortly afterwards, the electrically-driven compressor was adopted on the score of cheapness, as by this time the large electric supply companies of New York were in a position to offer cheap power.

The turbo-compressor, though at present looked upon as essentially a large-capacity machine, may in the future also compete with the small unit of the reciprocating type. A short chapter is given to a description of the turbo-compressor and a few general considerations of its design and construction. The next chapter is devoted to describing the Taylor compressor and the Humphrey pump; special reference being made to the Taylor compressor of 40,000 cub. ft. per minute capacity at Ragged Chutes, on the Montreal River, which supplies compressed air to the mines at Cobalt. Owing to the solution of a greater percentage of the oxygen than that of the nitrogen of the air while compressed in contact with the water, it is found difficult to burn candles in the mines supplied—the compressed air was proved by analysis to contain only 17.7 per cent. of oxygen, as against the 21 per cent. in normal pure air. The Humphrey pump is described, and its possibilities when applied to air compression instead of water-raising discussed.

A table giving the power required for the compression of air at constant temperature and without cooling is computed, and the various sources of loss are considered; and also tables and charts which afford a means of determining the consumption of steam per 100 cub. ft. of air compressed, on a basis of certain assumed steam consumptions per indicated horse-power hour on the steam side, are given.

A short chapter follows on "Power from Compressed Air," and then the function of air-receivers is considered, the author favouring a combination of after-cooler and water-extractor in one, with sufficient capacity (volumetric) to act also as the receiver; he also speaks for an increase in the size of receivers above that usually found in present-day practice, and describes the unique receivers of the plant for supplying air for the driving of all the hoists of the Anaconda Copper-Mining Company at Butte, Mont., in which the total capacity of the receiver vessels is utilised, and an almost absolutely constant pressure maintained, by the connection to the bottom of these vessels of a huge water-pipe connected up with a dam on an adjacent hill.

Continuing, transmission is dealt with, tables and formulæ being given for pipe-resistance for air under different pressures, and the advantages and limitations of re-heating are enlarged upon. Combustion of oil in receivers and pipe-lines take place at comparatively low temperatures, on account of the high pressure, and combustion of oil is shown to have started at 275 deg. when under a pressure of 65 atmospheres in the case of a receiver fitted with a recording thermometer. The author advocates the careful use of cylinder oil and the frequent cleaning out of receivers and other parts in proximity to the compressor, with a view to reducing the frequency of such occurrences.

Compression of gas for distribution is advocated in a chapter of considerable length, wherein is also made out a plausible case for the abolition of the gas-holder by boosting up the pressure in the mains and fitting reducers at points of consumption. The St. Louis and other high-pressure gas systems, and the natural gas transmission, 123 miles in length, to Cincinnati, are cited as proof of the success of high-pressure gas transmission and distribution. The gas in the latter case is drawn from 100 gas-wells supplied over some 300,000 acres.

The next two chapters are given to air drills in general, and to the "electric-air" drill, the performances of the latter during the construction of the great Kensico dam for the new water supply to New York City being quoted as an example of the high efficiency of this type of machine. Several more or less well-known compressed-air appliances are described, and data and calculations are given for the proportioning of the well-known "air lift" for water. Caissons, diving-bells, and allied applications of compressed air find a place, together with such apparatus as the air blast in its application to foundation sinking (which is carefully described), the sand blast, pneumatic painting, and the "cement gun." This last is interestingly described and explained.

A chapter on liquid air concludes the volume with diagrams and descriptions of the Linde and Claude oxygen plants and explanations of their processes.

To the practical engineer who, though thoroughly conversant with his own branch of the profession, has not had much experience of compressed air, this volume should prove of great value.

THE ALEXANDRA DOCK EXTENSION AT NEWPORT.

(*Continued from page* 37.)

HAVING dealt in our last article with the construction and general features of the dock extension and the new lock, we now propose to say something of the gates and their operating machinery, the fender-chain gear, and other mechanical appliances fitted in connection with the lock. The gates, which were constructed by Sir William Arrol and Co., Limited, of Glasgow, are of iron and steel, with greenheart heel-posts, meeting-posts, and sills. A characteristic example is illustrated in Figs. 47 to 53, on Plate XVI. The middle and outer gates are 49 ft. high by about 56 ft. wide. The inner gates are the same width, but 10 ft. less in height. Figs. 47 to 53 show one of the deeper gates. In general construction the gates may be said to consist of a series of girders or decks, of form in plan as shown in Figs. 52 and 53, and varying from 2 ft. 6 in. to 3 ft. 6½ in. apart vertically. The girders are placed closer together near the bottom of the gate, except that the bottom pair are 2 ft. 9½ in. apart. The distribution of the various girders is shown in Fig. 50.

At the vertical edges of the gate there are two box-frames built up of plates and angles, and carrying respectively the heel-post and meeting-post. These frames are shown in cross-section in Figs. 52 and 53, while one of them, in process of being lifted into position for the erection of a gate, is shown in Fig. 71, on page 112. As will be seen from this latter figure, the frame has a series of horizontal webs. These join up with the ends of the decks when the main girders are riveted in place. The method of building up and the construction of the gates will probably be better understood from Fig. 72, on page 112, in conjunction with Figs. 74 and 75, on page 113, than from any description. The two end frames and the bottom pair of girders were first erected, and the various girders, from the bottom upwards, then placed in position and riveted up. As will be seen from Figs. 74 and 75, the girders and the inner strakes of skin-plating were first erected, and the spaces between alternate pairs of girders afforded convenient access to the interior of the gates during erection. These spaces were closed by the outer strakes of skin-plating, which were fixed as the riveting of the skin-plating proceeded.

The webs of the girders, which form the decks of the gate, are in the majority of cases of lattice construction in the two centre panels, as shown in Fig. 53. Decks G, R, and V, however, are of plating throughout, as shown in Fig. 52. These decks divide the interior of the gate into water-tight compartments. Details of the method of joining the box-girders to the end frames will be followed from Figs. 49, 52, and 53. The vertical and horizontal plates of the two members form butt-joints, double cover-plates being placed on the webs, and outside cover-plates on the verticals. Inside cover-angles are used in each corner. The skin-plates, which form the intermediate strakes, form lap-joints with the verticals of the end frames. Caulking-strips are used over the cover-plate joints. The intermediate strake-plates lying over the vertical outer plates of the box-girders can be caulked completely round their edges. The appearance of the curved outer surface of the gates with the plating complete is shown in Fig. 77, on page 113. The other sides of the gates, which carry wood fenders, are shown in Fig. 73, on page 112. In connection with these fenders it should be noted that any blows which they may sustain from a passing ship, when the gate is standing open and lying in the recess in the lock wall, will be transmitted by the main framework of the gate direct to the vertical timber fenders upon the wall of the gate recess, against which the gate rests when fully open.

A series of manholes are provided through the various decks and vertical partitions, giving access for repairs and painting. Trunks fitted with ladders lead to the two water-tight compartments from the upper deck. The manholes in water-tight decks are fitted with water-tight covers. The upper portions of the trunks can be seen in Fig. 75, on page 113. Each gate is surmounted by a platform forming the footway, which is clearly shown in Figs. 68 and 69, on Plate XVI., and need not be described in detail. The flooring is of oak planking 4 in. thick. The platform under construction is also shown in Fig. 77, to which we have just referred. The trunks project from the upper deck to just below it, and square covers are provided in the flooring. Each gate is fitted with an ejector, operated from the high-pressure hydraulic mains, for the purpose of removing leakage and condensation water from the interior of the water-tight compartments. As stated at the beginning of this description, both iron and steel have been employed in the construction of the gates. All rolled sections are of steel, as are the braced decks and the vertical web-plates. The water-tight decks and all skin-plates are of iron.

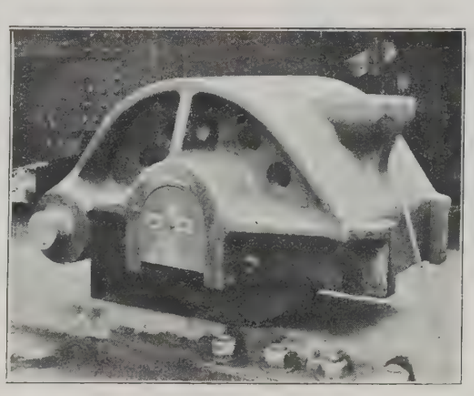

FIG. 70.

The supports for the gates are illustrated in Figs. 54 to 67, on Plate XVI. Figs. 54 to 60 show the upper bearing-bracket and its details. Fig. 54 is a plan of the complete bearing, while Figs. 55 to 57 are various sections. Fig. 59 is a plan of the anchor casting only, with the upper bearing-plate removed. The anchor-casting is secured to the well by two 5½-in. tie-bolts, which, as will be seen, are bent down, so that they distribute the pull over a large mass of concrete. Each tie-bolt carries two cast-iron washers, which lock it in position on the concrete formation. The distance between the two washers is about 18 ft. This length is much shortened in Fig. 56, in order to bring the figure within the limits of the page. The outer washer lies in a pit, furnished with a cover-plate, so that it may be got at from the quay. The type of washer used is illustrated in Fig. 61; it is 3 ft. in diameter. It will be noted that the tie-bolt shown in Fig. 56 carries a third washer at its outer end. This is a temporary fitting only, and was used for putting an initial stress on to the tie-bolts during setting up. This was achieved by using hydraulic jacks between the washers and the concrete wall. The temporary washer is illustrated in Fig. 60. As shown in Fig. 56, the tie-bolts are secured to the anchor-casting by means of cotters.

The upper pivot of the gate, which is shown in Fig. 56, is 2 ft. in diameter, works in a strap which runs right through the anchor-casting, and is secured by double nuts at the ends. The arrangement is clearly shown in Fig. 55. Above this strap-bearing for the gate-pivot there is a pin-bearing, 11 in. in diameter, which serves for the "crocodile" lever by which the pull or push from the operating engine is transferred to the gate. This lever is shown in Fig. 69, but is best seen in Fig. 75, on page 113, and Fig. 76, on the same page. The lever is free from the gate. At its inner end it has the independent bearing to which we have just referred. At its outer end it works between two vertical brackets fitted to the gate immediately over one of the vertical bulkheads, but is not secured to them. The arrangement is well shown in Fig. 75. The connecting-rod from the gate-engine is connected to the "crocodile" lever at a point about a quarter way along its length. The seats for its bearing-pin can be seen in Fig. 75. The object of the arrangement is to obtain a reasonably short stroke for the gate-engine, and at the same time to apply the force for moving the gate on the vertical line through the centre of pressure, and so minimise cross stresses as much as possible. It will be clear that as the "crocodile" lever is swung in or out by the gate-engine the gate will follow, owing to the brackets between which the outer end of the lever works.

Returning now to the gate supports, shown in Figs. 54 to 67, on Plate XVI., little more need be said of the upper anchor, as the purpose of the 11-in. pin-bearing will now be clear. It should be pointed out, however, that this bearing is carried in a cover-plate, which sits in a machined groove in the anchor-casting. The complete bearing can be removed without interfering with the anchor-casting, and the removal of the anchor-strap will then allow the gate to be removed for repairs if necessary. The lower gate-bearing does not need much comment. It consists of a hollow cast-steel socket with a forged steel bearing-plate, which works upon a cast-steel pivot secured by lewis-bolts to a granite bed-stone in the floor of the gate-chamber. The outer end of the gate is supported by a roller, which is illustrated in Figs. 63 and 64, on Plate XVI., and in Fig. 70, annexed. The arrangement consists of a cast-iron carriage with a pivot-pin at one end. The pin projects from each end of the carriage and fits into two round-ended notches cut in the plates which form the sides of the roller-box. These plates are, of course, part of the gate construction. The projecting pivot-pin can be clearly seen in Fig. 70. The carriage carries a cast-steel roller, 3 ft. in diameter at the centre, working in gun-metal bearings. The weight of the gate is transferred to the roller through the pivot-pin and through a spear-rod 6½ in. in diameter, which bears in a bracket cast on the top of the roller-carriage. The spear is clearly shown at the left-hand side of Fig. 64, and can be seen in section in Fig. 65. The spear runs up the front of the gate through guides which can be seen in Fig. 49, and in the general view given in Fig. 77, on page 113. At the top the spear terminates in a square rod which works between longer guides, which again can be seen in Figs. 49 and 77, and are detailed in Figs 62 and 63. Slots in the square rod and the guides and cotters serve to transfer the weight of the gate to the spear, from which it is transferred to the roller-carriage. The arrangement serves as an adjustment for wear of the roller-bearings. Such wear lowers the level of the outer end of the gate a little, and tends to put extra strain on the pivots, and affects the water-tightness. By driving in the cotters at the top of the spear the gate is lifted a little, and the wear allowed for. Details of the track on which the roller works are given in Figs. 66 to 68. The rail is of cast iron, and the foundation fish-plates are of cast steel. The track is held down by lewis-bolts.

Turning now to the gate-operating machinery, attention may be directed to the general plan of the lock given in Fig. 4, on Plate X., in connection with the first article of this series. It will be there seen that for each gate there is a long trench in the quay lying at a slope to the side of the lock and towards the

inner side of the gate. Each of these trenches contains an operating engine, which consists of a single hydraulic cylinder with piston, piston-rod, and crosshead, and a connecting-rod, which is directly connected to the "crocodile" lever already dealt with. The movement of the piston from one end of the cylinder to the other opens or closes the gate. It will be clear that the engines are very simple and straightforward affairs. They were supplied by Messrs. Glenfield and Kennedy, Limited, of Kilmarnock, and one of them is illustrated in Figs. 78 and 79, on page 114. Details are given in Figs. 80 to 87, on the same page. The cylinder is 1 ft. 9¼ in. in diameter with 12 ft. 9 in. stroke, and works with pressure water at 750 lb. per sq. in. As will be seen, the crosshead-guides are bolted to the cylinder, and the whole arrangement rests on four brackets, which are secured to granite blocks set in the concrete. The cylinder is fitted with a ¾-in. gun-metal liner. The connecting-rod, which is built up of angles and plates, has two 9-in. pivots at right angles to each other at each end. This not only provides for the natural inclination of the connecting-rod in a horizontal plane, but also allows for slight errors of alignment in a vertical plane, which might arise in setting up, or from settling of the gate with wear of its bearings. The engine is controlled by a slide-valve, which reverses the direction of water through it.

Our next series of figures—those on the present page—shows the fender-chain gear. Two such gears are fitted—one on the dock side of the inner gates, and the other on the river side of the outer gates. In the construction of the dock, however, grooves have been made on the other sides of these two gates and on both sides of the middle gates, so that a more complete fender-chain installation may be fitted in the future if desired. The general lines of the two gears fitted will be easily followed from the figures annexed. Fig. 88 is a plan of the whole gear, showing the two sides of the lock; Fig. 89 is a cross-section of the same thing. Figs. 90 and 91 are detail sections; while Fig. 92 is a small-scale cross-section of the lock, illustrating the principle of the appliance. To briefly describe the arrangement, it may be said to consist of a heavy chain, which normally lies in a groove at the sides and bottom of the lock, so that it does not interfere with the fairway. The ends of the chain are fixed to a winch and relieving gear, which are situated on opposite quays. When a ship is approaching the gates, the chain is

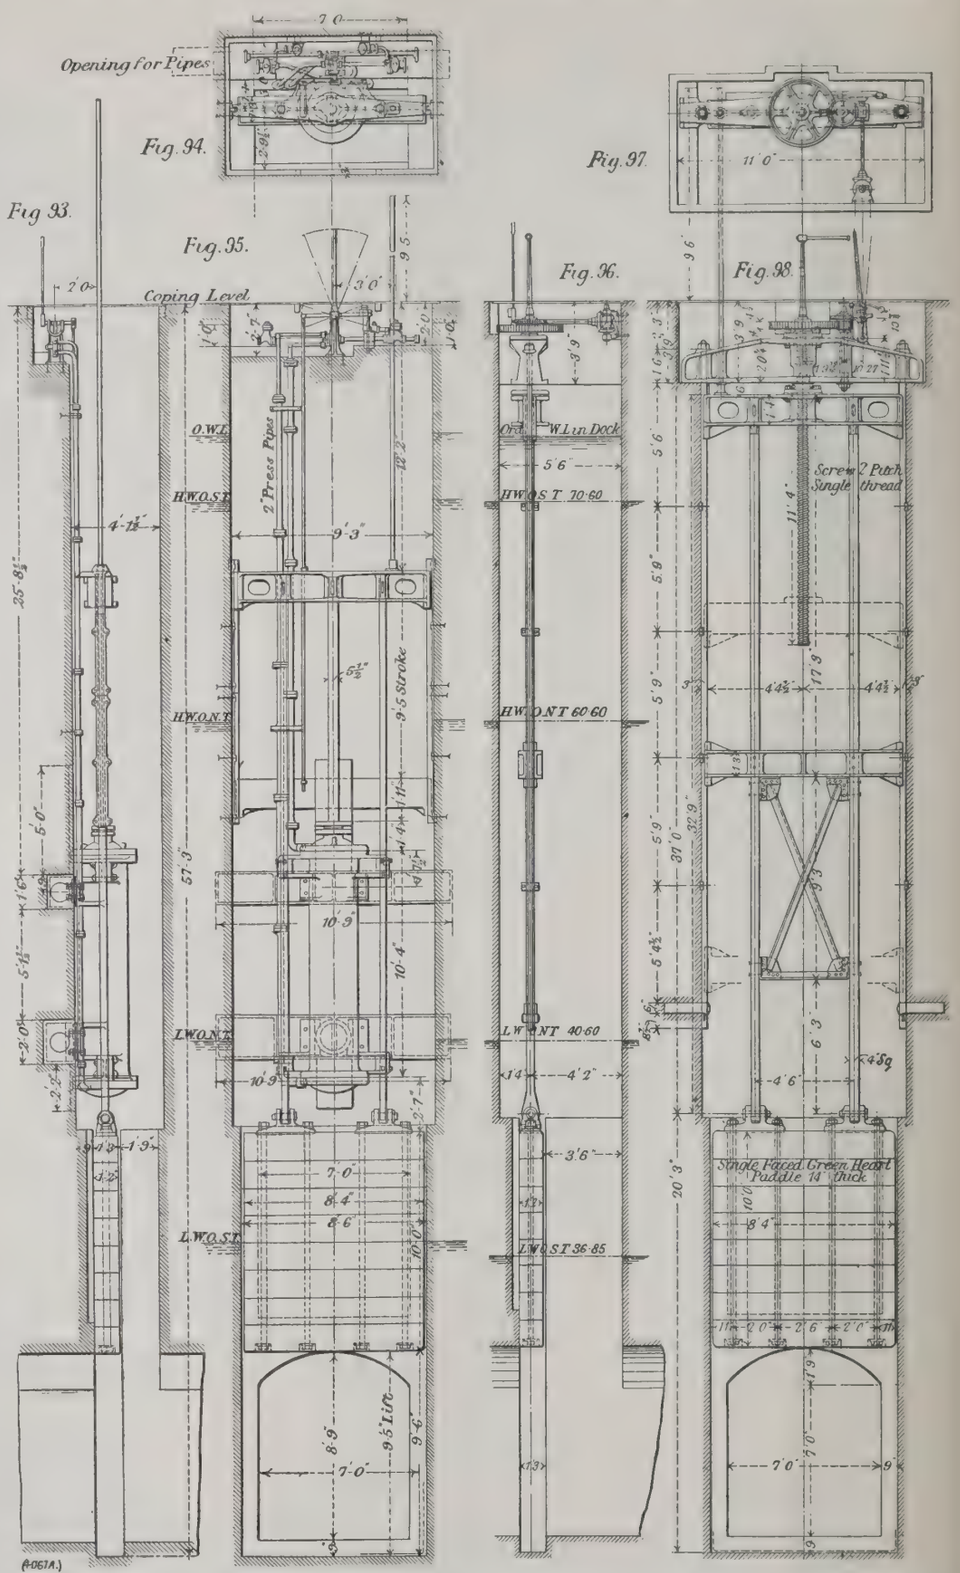
hauled in by the winch at one end (the other end being fixed) until it is stretched more or less taut across the top of the lock, as shown in the upper position in Fig. 92. If now the ship gets out of hand and charges the gates, it strikes the chain and is checked, so that the chain takes the blow instead of the gates. In order that the chain may not be broken by the sudden shock and to take the way off the ship gradually, the relieving gear, to which we have already referred, allows the chain to slip at a predetermined tension, which is maintained during the whole period of slipping, so that the ship is slowly stopped.

The gear by which these operations are carried out is shown in the figure. The winch has a grooved drum, 3 ft. 6 in. in diameter, driven through single gearing from an hydraulic engine having two pairs of facing cylinders, with rams $5\frac{1}{2}$ in. in diameter by 9 in. stroke. A hand-brake is fitted, and an automatic cut-off gear, which stops the engine when the chain is fully hauled in. The chain is led to the winch round a sheave, which can be seen at the left-hand side of Figs. 88 and 89. From the sheave it passes through a tunnel on the quay, and finally out to the lock by a hawse-pipe. The tunnel connecting the winch and the sheave is of taper form in plan, to allow of the horizontal movement of the chain as it is wound in and travels along the length of the drum. This tunnel has a $\frac{3}{4}$-in. steel plate for a flooring, on which the chain lies. The chain between the sheave and the hawse-pipe lies in a wooden guide. The two arrangements are shown in the section given in Fig. 91. The duty of the winch is to haul in the chain from its normal position at the bottom of the lock until it is stretched across the top. The winch is not designed to take the shock of a ship striking the chain, and, accordingly, when the chain has been hauled in, a chain-stop is brought into use which locks it in position. This stop can be seen in Figs. 88 and 89. It is fixed at the entrance to the hawse-pipe and consists of a fixed cast-iron block, anchored to the concrete formation, as shown in Fig. 89, and carrying a movable cast-steel block in a slot on its upper side. This movable block is operated by a hand-lever gear from quay-level. When the chain is being hauled in, the block is in its upper position and the chain passes freely. When, however, the chain is completely lifted, the block is moved down. This locks the chain, and any movement that the chain then makes owing to a ship striking it must be at the expense of the relieving-gear on the other quay.

The relieving-gear can be seen at the right-hand sides of Figs. 88 and 89. It consists of a pair of drums, mounted one above the other in square bearings carried by side frames in such a manner that neither drum can rotate. The upper drum is 1 ft. 3 in. in diameter, and the lower 2 ft. 6 in. The bearings of the lower drum are fixed in position, but those of the upper slide in guides in the side frames. A pressure is maintained between the two drums by adjustable spiral springs mounted above the upper one. The upper drum is parallel throughout its length, but the lower has flanges at each end. The chain enters by a hawse-pipe and makes several turns round the lower drum, as shown in Fig. 88. Leaving the drum, the chain is coiled in the pit behind the relieving-gear, and then makes a few additional turns round the lower drum. Its end is fixed to a staple in the floor of the pit. This arrangement as described normally does not move, but in the event of a ship striking the chain when it is taut, the relieving-gear slips and the chain is payed out by the lower drum under the tension induced by the pressure of the top drum and the friction of the first series of coils round the lower drum. When the whole of the slack has been paid out, the friction of the additional turns round the lower drum is brought into play, and this, together with the anchorage of the free end of the chain in the floor of the pit, ensures that the full strength of the chain is finally brought into use. There is one further point in connection with this gear which should be mentioned. When the chain has been hauled taut by the winch into the position indicated in Fig. 92, and is then released by reversing the winch to return to its original position in the groove, it will tend to pile up at the bottom of the lock on the winch side instead of distributing itself properly throughout the groove. To prevent this, a light chain is attached to it near its middle point, as shown in Fig. 92. This chain is hauled in by a capstan on the quay, and drags

NEWPORT DOCKS; EXAMPLES OF SLUICES.

SIR JOHN WOLFE BARRY, LYSTER AND PARTNERS, MM. INST. C. E., WESTMINSTER.



the chain towards the relieving-gear side of the lock, so that it settles down properly in the grooves. The main chain has stud-links made up of $1\frac{5}{8}$-in. material. The gear was supplied by Messrs. Glenfield and Kennedy, Limited, of Kilmarnock.

The final feature with which we propose to deal in this article is the sluices, characteristic examples of which are illustrated in Figs. 93 to 98, annexed. These figures show an hydraulic sluice and a hand-power sluice. Hand-sluices are fixed in all cases as stand-byes to the hydraulic sluices, except in the case of the sluices for the culverts leading to the future graving-dock. Hand-sluices only are fitted at the far end of the discharge-culverts leading from the power-station to the dock, and form stand-byes to the hydraulic sluices which are fixed upon the delivery-pipe of each pump in the power-station. There are in all thirty-four sluices. Eight of these serve for the control of the supply to or from the power-station pumps, in addition to the two hand-sluices, already mentioned, at the far end of the discharge culverts. The remaining twenty-four serve the double levelling culverts, which connect the pens of the lock and the lock with the dock and river. The positions of most of them can be seen from the plan of the lock given in Fig. 4, on Plate X., in our issue of July 10. The sluices, which are all of the same general character, were supplied by

Messrs. Sir W. G. Armstrong, Whitworth and Co., Limited, of Newcastle-upon-Tyne. The two types are illustrated in Figs. 93 to 98, on page 116. In both cases the paddles are of greenheart, 14 in. thick. The hand-sluices are operated by a worm and spur-gear which drives a main lifting-screw, working in a nut in the top crosshead. This crosshead and the lower work on guides keyed to the sides of the pit. An indicating-rod carried by the top cross-head projects above quay-level and shows the position of the sluice. The hydraulic sluices are operated by a direct-acting ram which is connected to a single crosshead. The details of both arrangements will be clear from the figures.

(To be continued.)

SETTING OUT WORK.

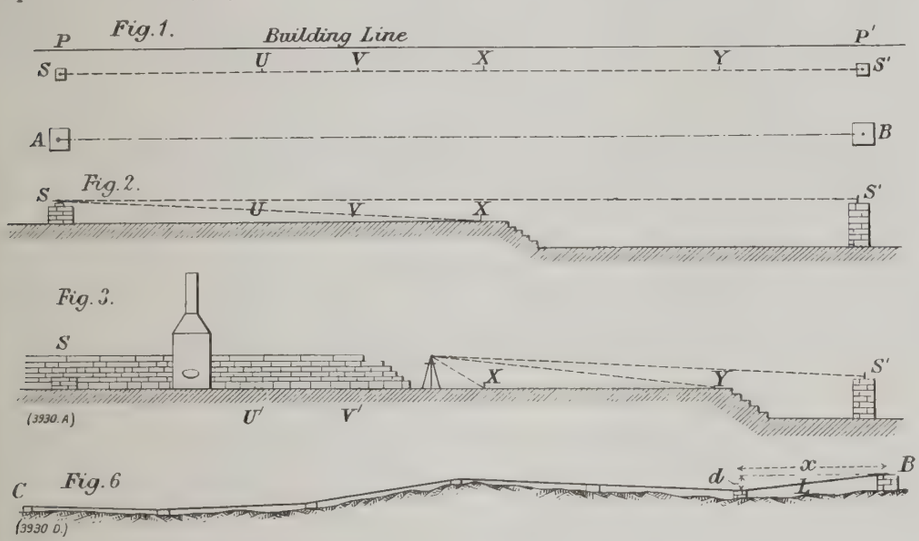
By R. H. LEE PENNELL, Assoc. M. Inst. C.E.

THE following articles are intended to form a guide to young engineers when they first come on to works after leaving college. Men just leaving college are probably fairly well grounded in surveying and the use of the ordinary surveying instruments; but the setting out of work differs considerably from surveying. In the latter operation the positions of existing objects have to be fixed in such a way as to enable them to be plotted on a plan, but in the former case objects have to be located on the ground in certain required positions derived from a plan. Setting out work is therefore an operation which is the reverse to surveying. The present articles are based on a short series of lectures given by the author, in Cairo, to the students of the Egyptian Government School of Engineering.

To Set Out a Straight Line.—The setting out of a truly straight line is a difficult thing to do; it has been said that anyone can set out a curve, but it takes an engineer to set out a straight line. The difficulty is that it is usually impossible to see the whole length at one setting of the theodolite, owing to gangs of workmen, stacks of material, cranes, &c, being on the line of sight. The theodolite therefore has to be set up more than once in order to complete the line it is desired to mark out.

Suppose the line to be set out is for the parapet wall and coping-stones of a long, straight breakwater. In Fig. 1 suppose P P′ is the building-line required. If you set out this line, your points will very likely get destroyed or obliterated with mortar as the masonry is built; also, if there is any bull-face on the stones, the points will be very awkward to build to after the first course is laid. It is therefore much better to set out your line as a parallel line to the building-line, and from 1 ft. to 2 ft. from it. At this distance it is easy for the masons to obtain their building-line with their 2-ft. rules from the points set out by the engineer.

In the figure, therefore, let S S′ be the line it is proposed to set out, within 2 ft. of the building-line, and let A B be the axis-line of the whole work. (This need not necessarily be the centre line; in the case of a dam with under-sluices it would preferably be on the line of the sluice-gates, but in any case all major work should be set out either directly or indirectly, the former for preference, from this line.)



At the theodolite stations A and B, mark off roughly the distances A S and B S′. Build temporary theodolite stations at S and S′, then very carefully set out and mark the points S and S′ on the pillars built.

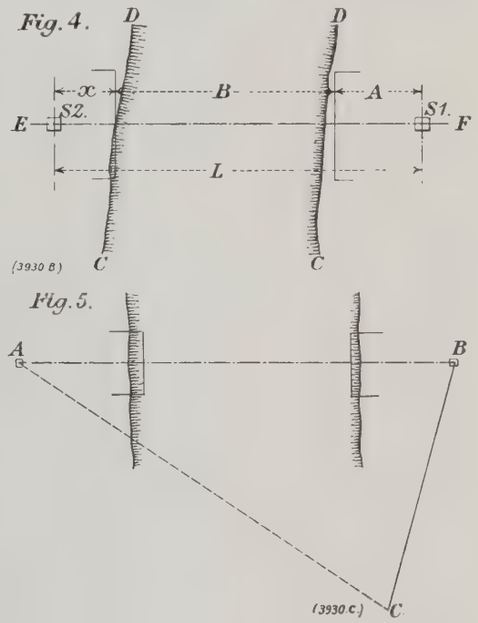
It should be quite easy to see from S to S′ direct. But when the line of sight is depressed, so as to mark the points on the line S, S′, obstructions will often be found in the way. Setting the theodolite up at S, therefore, and sighting on to S′, set out as much of the line as can be seen. Assume the first length is set out as far as X (Figs. 1, 2 and 3). It is now wanted to set out the length X Y. Since S′ should stand high, it will be visible from X (it is important that either S or S′ shall be seen from X, as it is very risky to continue the line relying only on the last points set out).

The obvious way to set out X Y would appear to be to set up on X, sight on to S′, and then put in Y. If you do this, you will almost certainly get a kink in your line at X; you may reverse and swing the theodolite, and take every possible precaution, and yet get a kink at X. Therefore do not set up on X, but some little way back from X, sufficiently far to have X in focus. There will be no point to set up on, but by ranging in the last two points V X, you must get as close as you can. Then sight on to S′ and down on to X; you will not strike X. Unclamp centre-plate and move the instrument over, and try again until, after sighting on S′, you strike X exactly.

When your cross-hairs cut both points X and S′ you are absolutely certain that your line of sight is on the line you require, and you can set out your points with confidence, even should the theodolite be slightly out of adjustment.

To Set Out the Abutments of a Bridge Across a River.—This in most cases entails triangulation, but whenever it is possible to measure directly, always do so. When direct measurement is possible, the procedure may be as follows:—In Fig. 4, C D and C D represent the banks of a river, and are, say, 150 ft. apart. E F represents the centre line of the approach roads of the bridge. It is required to set out the abutments. Select any two points S^1 and S^2 on the centre line E F, keeping these points well back from the top of the bank, and build these points in, in masonry, so as to avoid any fear of them being moved. The points must be kept well back from the banks of the river, as otherwise pile-driving, for example, might affect them by the tremor caused to the surrounding ground and so slightly move them out of position, or railroads for cranes or materials might unavoidably foul them. Then with a light steel measuring-wire measure the distance between these points as follows:—

One man holds one end of the wire 1 ft. back from the base point. A second man kneels over the base point to see that the 1-ft. mark on the wire exactly coincides with the point. (This is much easier than getting the point and the edge of the handle to coincide.) On the other bank an ordinary spring-balance is attached to the wire, and on this a man pulls hard, the wire passing over the base point. Over the low masonry pillar carrying this point the engineer stands with a pencil. (It is assumed that only even feet are marked on the wire.) The engineer watches the man over the base point on the far bank, and when the latter signals "right," the engineer shouts to his man to read the spring-balance, and he himself, with his pencil, marks the position on the pillar of the nearest foot-talley on the wire. He then reads this talley, and the men slack off. The operation should be repeated at least once, the man with the spring-balance this time pulling until he reads the same tension as before on the balance, the engineer marking the pillar as before.



This operation all finished, the engineer measures the distance between the mean of his pencil-marks and the base point. This is obviously either an addition or a subtraction to the measurement by wire. A correction for the sag of the wire has then to be made by measuring a similar length on level ground with a standard tape. The tape should be laid along the ground for a few minutes with a thermometer near it, so as to correct for the temperature of the tape. The steel wire is then stretched over the measured length at the same tension as before, and the length noted; of course, the wire must not touch the ground.

Since the whole length of wire is thus checked, any light steel wire will suit the purpose in the original measurement (if a proper measuring wire is not available), a spot of black paint and a scratch mark at the ends marking the measuring points. The only difficulty in the whole of this operation is the checking of the wire for sag, which will require two plumb-bobs and plenty of men to pull long and steadily. The easiest way is to stretch the wire first and mark the length very carefully on two wooden pegs, or otherwise, and then to measure the length between the two points thus obtained, as described above.

The distance between the two pillars having been obtained, and the position of one abutment settled upon, the position of the other abutment is fixed by measuring back from the pillar. In Fig. 4, $x = L - (A + B)$.

Remember that when setting out, in order to start excavation, it is no use bothering about a few inches one way or the other, and that accurate setting out is not required until the foundations go in. In the case of a bridge, the foundations and lower courses of the abutments will probably be below water level. Setting out such work will be considered later.

If the river is too wide to measure directly across, it is necessary to triangulate it and calculate the length. Two pillars are built as before, and a base line B C measured (see Figs. 5 and 6). The measurement of base lines is fully treated in most text-books on surveying, and a few notes only will therefore be given here.

Do not try to set out the base B C at right angles to the axis. It is much easier to read an angle than to set an angle out correctly. In any case, read all the angles of every triangle and each angle at least three times, and read continuously. Do not attempt to set the instrument back to zero each time.

When measuring the base line, use special base-measuring instruments, if possible; should these

not be available, the following notes may be found useful :—

Level off small irregularities in the ground from B to C (Fig. 6). Set bricks at from 15-ft. to 20 ft. intervals along B C and work them well down on to an even bed. The bricks should be set to line with the theodolite.

Take the level of each brick.

See that the tape when measuring touches the top of each brick ; note where each brick occurs, but measure continuously ; if any full tape length overshoots a brick, book the length to the brick, and start off the brick again.

Keep the tension on the tape constant with a spring-balance.

Have a very good man at the zero end of the tape.

Unskilled helpers may be used to hold the tape down on to the intermediate bricks by pressing on to it with one finger only. If your tape sags between the bricks, more bricks must be put in. Having measured your total length B C, correct same for horizontal distance. In the first length of exaggerated figure (see Fig. 6) :—

d = difference in level of two consecutive bricks.
l = measured length.
x = required length.

$$x^2 = l^2 - d^2.$$

Having obtained the total horizontal distance, next correct for temperature of tape.

(total distance) × (coefficient expansion) × (temperature on ground—standard temperature) = correction.

Theoretically the temperature correction should be applied separately to each length between bricks, but the error involved as worked above is negligible. The standard temperature will probably be freezing-point. The tape will therefore be too long.

This brings us to an important point. Is this correction an addition to or a subtraction from the length ?

This depends upon whether you have fixed the point C. and are measuring between B and C to obtain the distance, or whether you have settled to put C in at a certain distance from B on the line B C. The former measurement is practically a survey measurement. The latter measurement is a "setting out" measurement. In the first case, if you have fixed the point C, and are measuring between B and C to find the distance between them, you must add your correction for your tape being too long. In the second case, if you wish to set out C at any fixed distance from B, you must subtract your correction for the tape being too long. Taking an example :—For simplicity, suppose the length from B to C, in the first case, happened to measure 600 ft. by the tape. The thermometer on the ground registered 82 deg. Fahr. The tape was an ordinary steel tape with coefficient of expansion of 0.00000661, and standardised at freezing-point; the correction will be

$$600 \text{ ft.} \times 50 \text{ deg.} \times 0.00000661 = 2\tfrac{3}{8} \text{ in.}$$

The distance between B and C will really be, therefore,

$$600 \text{ ft. } 2\tfrac{3}{8} \text{ in.}$$

But in the second case, if you wish to mark the station C at exactly 600 ft. from B, and the same conditions as above prevail, you must put the point C in at 599 ft. $9\frac{5}{8}$ in., according to your tape markings. Having measured the base-line, measure the three angles of the triangle as already described. The length of the axis-line between the two pillars can now be calculated, and the abutment lines set out as before.

(*To be continued.*)

THE PANAMA-PACIFIC EXHIBITION.—From September 20 to 25, 1915. there will be an important congress of engineers at San Francisco, Cal., U.S.A., in connection with the Panama-Pacific Exhibition. This congress will be presided over by Colonel G. W. Goethals, and representatives of a large number of countries are expected to be present. The leading American technical institutions are co-operating to make it a success. Undoubtedly one of the most interesting features of the congress will be the presentation of papers dealing with the Panama Canal itself. The contributions on this subject will be presented under twenty-two heads, among which are to be a general report by Colonel Goethals, and an account of the dry excavation, dredging, terminal works, design of locks, &c.; construction of same, the gates, dams, geology of the Zone, &c. These reports, all given under the supervision of Colonel Goethals, will be drawn up by the heads of departments in charge of the particular work described. They will constitute the only procurable official technical record of the construction of the canal.

INDUSTRIAL NOTES.

A MEETING of members of the Federation of Master Cotton-Spinners' Associations (American Section) was held on the 17th inst. at the Coal Exchange, Manchester, with a view to consider a recommendation from the General Committee of the Federation that between July and the end of September next production should be curtailed to the extent of stopping 166½ hours. Firms representing 70 per cent. of the American section attended the meeting.

Sir Charles W. Macara, President of the Federation, opened the discussion, and stated that the object of the meeting was to grapple with a state of things which, unless resolutely dealt with, would land them into difficulties greater than they could possibly imagine. As they looked round the manufacturing districts they saw that looms were stopping in every direction, and if spindles were to continue running in the conditions which now prevailed they would soon be in a state of absolute chaos. He maintained that organised effort, with the burden spread over the whole trade, was infinitely better than any individual effort could be, and would effect the purpose they had in view—*i.e.*, the restoring of the trade to a stable basis, sooner than any industrial effort possibly could.

Referring to the position of the cotton trade in other countries, a statement received from the Secretary of the International Federation of Cotton-Spinners was read. In this it was stated that the cables received showed that in several of the countries the lead set by England in former years as regards short time had been followed. If Lancashire on this occasion adopted the proposed curtailment, it would undoubtedly stimulate other countries to adopt and extend the short-time movement.

Sir Charles therefore moved :—"That this meeting of members of the American Section of the Federation strongly approves of the recommendation of the General Committee that spinners of American cotton should stop their mills for 166⅔ hours, exclusive of holidays, between July 7 and the end of September, and that a circular be issued to ascertain if firms owning the necessary percentage of spindles (80 per cent.) are willing to curtail production, in accordance with the recommendation."

The resolution was seconded by Mr. J. B. Tattersall, Vice-President of the Federation, who appealed for a united effort. It was passed, with one dissentient.

A circular was then sent to all federated firms, appealing to them to support the resolution by filling in their voting paper in the affirmative.

The German textile industry also appears to be in a difficult situation, since a general lock-out of men and women employed in the Lusatian textile mills was declared on Saturday last, the 18th inst. At Kottbus about 5000 to 6000 employed in 50 factories, and at Forst 10,000 to 12,000 hands employed in 120 factories, were locked out. A number of discharged hands belong to the towns of Sprenberg, Guben, Luckenwalde, Sommerfeld, and Finsterwalde.

We are informed that Messrs. Lever Brothers, Port Sunlight, have increased the wages of several grades of their employees. Wages of labourers have been raised from 26s. to 28s. per week ; process labourers will now earn a minimum of 30s. ; the wages of girls over twenty-one years of age, and counting at least three years' service, have been raised from 14s. to 16s. per week ; the wages of youths have also been increased.

In our last issue, on page 96 *ante*, we referred briefly to the difficulty which had arisen with the men employed by the Mersey Docks and Harbour Board. On Friday last, the 17th inst., the Strike Committee issued the following statement :—

In our various letters to the Dock Board up to June 4 we merely asked for recognition of the Union by the formation of a joint or conciliation board, equally representative of the Board and the workers, feeling confident that if that had been granted we would have avoided the present trouble.

The reply of the Board was a direct refusal to meet or discuss the question with them. We then placed the Board's reply before their employees at mass meetings held on June 28 and July 5.

At these meetings the members assembled, and after discussing the Board's refusals, unanimously passed resolutions demanding recognition of port rates and conditions, and at the same time, in view of what might take place in case of a further refusal from the Board, they decided that the whole of the workers under the Board should, in their own interests, become members of some union, and that those members who were at the time in arrears to their respective unions, should make themselves full-benefit members, in order to secure full support during the strike.

The result of the mass meetings was forwarded to the Board in a letter on July 6, as follows :—

Gentlemen,—It is the earnest wish of the Engineering and Shipbuilding Federation and the Transport Workers' Federation to prevent a disruption on the Dock Board estate. Since our last letter the whole of the men employed by your Board have been consulted, and the following resolution unanimously passed :—

That this meeting of Dock Board employees endorses the policy as laid down by the union members employed by the Board :—

1. That a joint board be appointed for the settlement of all disputes.

2. That the port standard rate of wages shall obtain.

3. Agrees that all men employed by the Board shall of necessity belong to their respective unions, and in the light of eventualities be clear on the books of the same.

They further pledge themselves that if, in the judgment of their leaders, drastic action is necessary, they will support such action by all means in their power.

In view of this we are again instructed to request you to receive representatives of the above Federations to discuss the position as early as possible.

(Signed) T. GRIFFITHS,
JAMES STEPHENSON,
Joint Secretaries.

"This," the statement adds, "was in order to warn them of the impending trouble, and apparently our efforts to save the present situation have been wrongly used by the Board to complicate the issue. We therefore reiterate that we have not at any time asked or intended to imply, either directly or indirectly, that the Board should be responsible for anything beyond the fact that the men employed by them should be paid wages in accordance with the established rule of the port."

Later news received from Liverpool at first tended to show that matters were improving. The Strike Committee had held numerous sittings, and had been in constant communication with the Dock Board with a view to settle the dispute. At the time of going to press we learn that the Committee met again on Tuesday to await a communication from the Dock Board. This was received, but it did not prove satisfactory to the men.

On Saturday, the 18th inst., the Joint Committee of the Engineers' Societies distributed among the members on Tyneside a communication pointing out that the wages of sea-going engineers were less to-day than those paid to men holding similar positions 30 or 40 years ago. Recent experiences had proved to them the futility of individual effort, and the only means whereby important concessions could be secured was by the power of combination.

On the same day there were about 60 steamers, including 20 colliers, held up in the Tyne ; these ships were unable to get to sea owing to the engineers having handed in their notices. Six colliers having completed their cargoes before the 24 hours' notices expired, left the river. Some of the men decided to leave the boats as they arrived in London, and others, who reside on Tyneside, were to return with the vessels and terminate their engagements on their arrival. The seamen are lending support to the engineers, and decline to work with "blacklegs."

The Marine Engineers' Association, South Shields, have stated that the owners would be unable to secure engineers on the Continent even if the vessels were towed there, as the British engineers had an alliance with the foreign engineers, who were loyal trade unionists.

All shore fitters engaged in ship-repairing work on the Tyne ceased work last week, with the exception of those employed on oil-tank steamers and on foreign-owned vessels. The number of men affected is approximately 2000, in addition to about 300 marine engineers. The number of vessels held up in the Tyne is increasing, and it is expected that the dispute will extend to other British ports.

The following remarks are taken from the last issue of the *Moniteur Industriel* :—One of the French Chambers of Commerce recently adopted a resolution in view of the excessive number of social laws passed by Government. In this the Chamber asserted their desire to see improvements made in labour conditions, but express the view that the number of social laws increases every year, and by restricting production or by placing fresh burdens upon it, increase the cost of output and the cost of living. The resolution proceeds to "ask Parliament to show more prudence in future with regard to the adoption of fresh social laws, and not to put in force any new regulation concerning labour if a similar regulation be not adopted simultaneously by the other industrial nations." The so-called social laws, adds our contemporary, increase the price of all necessary articles and react upon those they were destined to assist. When the power of production of an industry is weakened legislatively, and when the taxes with which that industry is encumbered are raised, the cost of living is increased and no real benefit is derived from the measure. No

measure has yet succeeded in France in checking the exodus of labour from the land to the towns; there is an excess of urban workers, and in order that they all may live, the power of production of each has to be reduced, the wages remaining at the same standard. Such methods are ruinous to the nation.

Since we reported, on page 43 *ante*, that the Financial Committee of the French Senate had rejected the proposal for the Saturday half-holiday for State employees, Parliament has taken up the matter afresh, and, according to our contemporary already mentioned, the Senate has voted the reduction of working hours per week to forty-nine—*i.e.*, five days at nine hours and four hours on Saturdays—for State employees. The private firms throughout the country, it is believed, will have to adopt the same measure.

The dispute in the London building trades remains unsettled. A large number of the men involved held a meeting in Trafalgar-square, London, last Sunday, the 19th inst., and announced their intention of carrying on the dispute until the employers deleted the entire clause relating to disability. A minimum for the various grades was also demanded. The speakers further announced that the disability clause had undermined trade union liberty of action with regard to the non-unionist element, and although the struggle had been in progress for six months they had no intention of coming to a settlement until the point was satisfactorily dealt with.

The Home Secretary has issued the draft of an Order which he proposes to make under Section 116 of the Factory and Workshop Act, 1901. The effect is to require particulars of work and rates of wage to be given to all persons paid by the piece who are employed in factories and workshops in which the manufacture of articles of metal (not being machinery) is carried on, or who are employed in that class of work as outworkers. The Order will consolidate and supersede the existing Orders relating to the making of pens (July 12, 1900), the making of locks, latches, and keys (July 14, 1902), the making of chains, anchors, and cart gear (July 14, 1902), the making of iron safes (April 29, 1911), and the making of files (December 23, 1911). It is drawn so as to apply to the same classes of work (other than the manufacture of machinery) as are covered by the definition of "metal works" in paragraph (13) of the sixth schedule to the Act, with the inclusion, however, of workshops as well as of factories. It will not apply to any of the other works (*e.g.*, blast-furnaces, copper mills, iron mills, or foundries) defined in the other paragraphs of that schedule; nor will it apply to any work to which the Order of September 23, 1907, relating to the mixing, casting, or manufacture of brass or articles of brass, and the electro-depositing of brass, applies.

The Chief Registrar of Friendly Societies has issued his Report on Trade Unions for the year ending December 31, 1912. From this we find that during the year 1912 thirty-nine unions were added to, and thirty-six were removed from, the register; of these latter, twenty-three furnished notices of dissolution, eight were amalgamated with other unions, and in five cases the certificate of registry was cancelled at the request of the unions. There accordingly remained on the register on December 31, 1912, 683 unions, of which 576 were registered in England and Wales, thirty-one in Scotland, and seventy-six in Ireland. The 683 unions in question had a membership of 2,597,772. In 1903 the unions numbered 742, with a membership of 1,575,375; these figures show a decrease of fifty-nine unions, and an increase of over one million in membership. Among the unions showing the largest increase in membership during the year 1912 we may mention the National Amalgamated Union of Shop Assistants, Warehousemen, and Clerks, with an increase of 42,694; the Amalgamated Society of Engineers, 22,529; the Amalgamated Society of Railway Servants, 15,486; and the Amalgamated Society of Carpenters and Joiners, 12,600. On the other hand, three unions showed a decrease in membership, as follows:—The London Carmen's Trade Union, a decrease of 18,405; the Dock, Wharf, Riverside, and General Workers' Union, 14,771; and the Lancashire and Cheshire Miners' Federation, 9326. Taking the unions having the largest membership in the year under review (1912), we find the Amalgamated Society of Engineers with 143,998 members; the Durham Miners' Association with 136,966; the Amalgamated Society of Railway Servants of England, Ireland, Scotland, and Wales, with 132,002; the South Wales Miners' Federation with 114,208; the Yorkshire Miners' Association with 99,632; and the National Union of Gas-Workers and General Labourers with 82,135. The total income of the unions in 1912 was 3,845,841*l.*, 90.4 per cent. of which was contributed by the members, 4 per cent. by other trade unions, the remainder, 5.6 per cent., being interest on invested funds and contributions from other sources. The average contribution per week received from each member was 6 5d. The total funds of the unions on December 31, 1912, was 5,617,927*l.*, showing a decrease of 708,785*l.* during the year; this decrease in funds was due to the coal strike, and applied mostly to the funds of the mining group of unions. Taking the six unions at the top of the list, we find that on December 31, 1912, the Amalgamated Society of Engineers had total funds to the amount of 786,320*l.*; the Amalgamated Association of Operative Cotton-Spinners, 500,724*l.*; the Amalgamated Society of Railway Servants, 379,025*l.*; the Derbyshire Miners' Association, 244,022*l.*; the United Society of Boiler-Makers, 227,145*l.*; and the Associated Society of Locomotive Engineers, 169,712*l.*

NOTES FROM THE UNITED STATES.

PHILADELPHIA, July 8.

A RETROSPECT of the past six months reveals a very irregular course in iron and steel so far as demand went. Prices sagged irregularly; output varied from 75 to 50 per cent. of capacity. The lower tariff did not materially affect conditions. None of the anticipations came true. Export trade, especially in rails and pipes, shows improvement. A further growth of the export trade is clearly seen. June orders for cars foot up about 25,000, which call for 275,000 tons of steel, and the roads need much more rolling-stock. The total of rail export orders for June reached 75,000 tons, besides a few small unreported orders. Much railroad construction is contemplated in most of the countries taking these rails. A supplemental pipe order of 10-in. pipes is under consideration for Persia. It is definitely known that there would be considerably more business done if manufacturers were willing to sacrifice future possible profits, and take third and fourth quarter orders at current quotations. Experts in the steel trade see highly encouraging conditions in the near future, all based on the very patent fact that production is not much more than half normal production, and that demand has been repressed to the utmost limits. Everywhere the talk in the steel-using industries is over the uncertain trade conditions. This uncertainty is largely imaginary. The daily rush of small structural steel orders is rather surprising, in view of unsettled conditions generally. Much steel is wanted for small bridge work. All of the shipyards are crowded, and most of them, according to to-day's summary, have upwards of a year's work.

PERSONAL.—Messrs. S. H. Morden and Co., Limited, state that their address is now Morden House, Dartmouth-street, Westminster, S.W., close to St. James's Park Station, Underground Railways.—Messrs. Morris and Lister (London), Limited, have now taken over the sole representation for London and the South of England for Messrs. Miokelwright, Limited, of Alperton, in place of Mr. Raymond Smith, the late representative. All inquiries, &c., should now be sent to Messrs. Morris and Lister (London), Limited, 3 and 4, Palace Chambers, Bridge-street, Westminster, S.W.

THE SEVENTH INTERNATIONAL AERONAUTICAL CONGRESS.—The seventh International Aeronautical Congress will be held between September 27 and October 1, at the Lyons Exhibition. The Congress, which will be presided over by Lieut.-Col. P. Renard, will be held under the auspices of the Aéro Club du Rhône et du Sud-Est, and of the Municipality of Lyons. Many contributions of importance have been promised, from, among others, the following authorities:—MM. R. Soreau (France); Commandant Mathieu (Belgium); A. Sée (France); Adhemar de la Hault (Belgium); Capt. Costanzi (Italy); M. Joukowsky (Russia); General de Wendrich (Russia); M. Rinine (Russia); Ch. Maurain (France), &c. Further particulars may be obtained from the Aéro Club du Rhône et du Sud-Est, 4, Quai de la Pêcherie, Lyons, or of the Commission Permanente Internationale d'Aéronautique, 19, Rue Blanche, Paris.

THE LATE MR. HENRY JOHNSON.—We regret to have to record the death, on the 16th inst., of Mr. Henry Johnson, formerly of the Indian Public Works Department. Mr. Johnson was born in 1837, and from 1853 to 1858 was articled to Mr. J. Hodgson Jones, M. Inst. C.E., Westminster, during which time he was engaged on water, gas, and drainage works. He then went out to India as assistant engineer under Messrs. Brassey, Wythes and Co., on the construction of the Eastern Bengal Railway, having charge of 10 miles of line, including Barrackpore Station. In 1862-63 he was engaged in a survey of Zemindaries for Messrs. P. Watson and Co., Bengal, and then joined the Oudh and Rohilkund Railway, and, under Mr. J. E. Wilson, chief engineer, was first employed on survey, and then as assistant engineer on the line between Lucknow and Cawnpore. In 1866 he obtained an appointment in the Public Works Department, and after being in charge of road and barrack construction was transferred to the Indian State Railways. He had executive charge on the north side of the construction of the Chenal Bridge with the workshops required for its erection. Mr. Johnson was a member of the Institution of Civil Engineers, but retired from that body some years ago.

THE LATE MR. ROBERT COCKBURN.

MANY engineers have learnt, with much regret, of the death of Mr. Robert Cockburn, who, like his father, had long been closely identified with the design and manufacture of steam-valves and other accessories for marine engines. Mr. Cockburn had not for some time attended so actively to the work, owing to illness, but he was able to enjoy life up to the end. His death, sudden and unexpected, occurred at his residence at Blackdales, Largs, on Friday, the 10th inst. He was the son of Mr. David Cockburn, who instituted the well-known Cockburn valve works which are now situated at Cardonald, Glasgow. It was at his father's works that the late Mr. Robert Cockburn served his apprenticeship. He continued in employment in the same works, and in 1889 the business was transferred to him. Ten years later a private limited-liability company was formed, and Mr. Robert Cockburn shortly thereafter was appointed sole managing director, a position he held until his death. Under his management the business has been from time to time enlarged considerably; it was started with a mere handful of men, and now there are over 300 workers, the establishment covering 3½ acres. Mr. Robert Cockburn was buried in Millport, one of the Clyde watering places, in which he had for many years taken a part in public affairs, rendering useful service as a town councillor, and, for a term, as provost or chief magistrate. Mr. Cockburn was also a member of the Bute County Council, and a Justice of the Peace for that county. He is survived by a widow and one son and daughter, the son, Mr. David Cockburn, being assistant managing director of the company.

TORPEDO-BOAT-DESTROYER FLOTILLA LEADERS.—The two flotilla leaders recently provisionally ordered of Messrs. Cammell Laird and Co. and Messrs. W. Denny and Brothers are to be named Kempenfelt and Nimrod respectively.

THE COPPER MARKET.—In their report dated the 16th inst., Messrs. James Lewis and Son state that Standard copper advanced from 61*l.* for cash on the 1st inst. to 62*l.* 10s. on the 7th. The receipt of the American refiners' statistics, giving the home consumption for the month of June as only 20,637 tons, with an increase in the stocks of 9719 tons, induced large realisations, and values fell rapidly until 61*l.* was again accepted on the 14th. On the 16th inst. the closing quotations were 61*l.* 2s. 6d. cash and 61*l.* 11s. 3d. three months prompt. In the early part of the fortnight, American electrolytic copper was freely sold by leading producers at 10s. below the price of Standard, considerable quantities being taken by American consumers at 13⅛ cents per pound, and by European manufacturers at 63*l.* 10s. per ton c.i.f.; 13⅝ cents and 64*l.* being subsequently paid. With the fall in Standard, present values were 13⅝ cents and 63*l.* 5s. per ton. The total increase in American and European stocks during June was 10,995 tons. Production was steadily increasing, while consumption in Europe was not likely to continue on the same scale as that of the past half-year, Supplies to Europe had increased this year as compared with last, 33,351 tons, or over 14½ per cent. European consumption had apparently increased 33,220 tons, or 18½ per cent. Exports showed a falling off of 8195 tons, 2700 tons of which was due to reduced shipments to the United States, and 1828 tons to diminished shipments of sulphate. European stocks had increased 5296 tons, against a decrease last year of 2366 tons. American stocks had increased this year 6550 tons, against a decrease of 23,436 tons, the production being 11,583 tons larger.

THE JUNIOR INSTITUTION OF ENGINEERS.—A party of members of the Junior Institution of Engineers paid a visit last Saturday afternoon, the 18th inst., to the Tunnel Cement Works, Purfleet. The party were shown round the chalk quarry, and the mills in which the chalk and clay are washed and ground to the thick slurry from which the cement clinker is made; they witnessed the burning of the clinker in two rotary kilns, each 210 ft. long. They also saw the mills for grinding coal-dust, and how the firing of this dust takes place in the kiln; the cement-mill in which the cement clinker is ground; the cement stores, where the cement is packed by means of patent dustless vacuum packers exilors; and the power-station, with water-tube boilers and turbo-generators. With regard to the power-house, the 1200-kw. turbo-alternator is of the A.E.G. impulse type, and a favourable steam consumption of 13.8 lb. per kilowatt hour on full load, with a cooling-water supply of five gallons per pound of steam, has been obtained. An interesting feature is the way in which the motors have been assembled in special motor-rooms, so that they are, in a large measure, protected from the dust inseparable from cement manufacture. It has by this means been found practicable to use open-type motors. A certain amount of dust is, of course, inevitable, and the motors have, therefore, been provided with special insulation and dust-proof bearings, with heavy cast inspection covers. The switch-gear is of a most substantial type throughout, all motors being provided with oil-immersed controller-type starters, with self-contained resistances. The smaller motors are fitted with air circuit-breakers in dust-proof cast-iron cases, and the larger machines with sheet-iron switch-pillars containing oil-switches.

200-TON CUTTING-OUT AND FORMING PRESS.

A NEW form of double-crank press recently brought out by Messrs. Taylor and Challen, Limited, of Derwent Works, Constitution Hill, Birmingham, is illustrated on the present and opposite pages. The press is intended for cutting out and forming fairly long sheet-metal articles, such as window frames, troughing, &c. It is built up of two side frames, connected at the bottom by a heavy casting forming the bed, and at the top by two joists, placed with their webs vertical. The slide carrying the press tools works between adjustable guides on the side frames, and derives a reciprocating motion from a crank-shaft above it. These details are well shown in the various figures. The lower ends of the two connecting-rods, which drive the slide, are pivoted to the upper ends of adjusting-studs, which are carried through the upper part of the slide and through worm-wheels which have a threaded central hole. The worm-wheels are driven by two worms which are fixed on a common shaft, and are in turn driven by a further worm-gear from a hand-wheel. The hand-wheel and shaft, with the two main worms, can be clearly seen at the front of the slide in Fig. 1, while the details of the whole arrangement are shown in Figs. 3, 4, and 7. Rotation of the hand-wheel operates the two main worm-wheels, and so raises or lowers the slide on the adjusting-studs, which are prevented from turning during this operation, as they are provided with guides at their upper ends, as is shown in Fig. 3. The arrangement gives a total adjustment of 4 in. in the position of the slide.

The slide is balanced by a box of counter-weights placed on top of the machine. This box is provided with two guides, which can be seen projecting above it in Fig. 1, in which it is shown in its lower position. The guides are also shown in Figs. 2 to 6. The counter-weight box is lifted by four vertical rods, two at each side, as is best shown in Figs. 1 and 4. They work in guides, and are connected at their lower ends to a flat horizontal bar. As will be seen from Figs. 3 and 4, the slide is connected to this bar by two wire ropes, which pass over pulleys carried on the upper part of the framing. It will be clear from the figures that as the slide falls the counterweight rises, and *vice versâ*. This balancing arrangement takes all back-lash out of the slide, so that it does not drop when cutting through a plate. This considerably prolongs the life of the cutting edges of the tools. The balancing is also of advantage in connection with the adjustment of the slide, as it allows it to be moved either up or down with equal ease.

The crank-shaft is driven by a cut spur gearing, of which the spur wheel can be seen at the left-hand side of Fig. 1. The pinion is fixed on the driving-shaft, which runs along the back of the machine, and carries the driving-pulley at the other end. A fly-wheel is fixed to the pinion-shaft at the right-hand side of the machine. It is provided with holes in the rim for barring when setting up. The whole of the driving-gear is well shown in Figs. 2 to 7. The driving-shaft runs at 160 revolutions per minute, the gearing ratio is 6 to 1, and the press makes about 26 strokes a minute. As will be seen from several of the figures, the machine is provided with fast-and-loose pulleys and a belt-shifting hand-lever. This gear is only used when the machine is first started, or when it has to be stopped for some time.

For the intermittent starting and stopping, which is necessary for the removal of a formed piece of work and the insertion of a new blank when the press is working, a gear altogether independent from the belt-shifting gear is provided. This is controlled by two hand-levers, both of which have to be operated, so that there is no possibility of the workman starting the press when one of his hands is in such a position that it may be crushed by the down-coming slide. The starting-gear operates a clutch situated in the boss of the large spur-wheel. This clutch consists, in essence, of a spring-controlled key sliding in a slot formed in the shaft which carries the spur-wheel. The position of the key is controlled by a sliding cam-plate, which embraces the shaft, and, in turn, the position of the cam-plate is controlled by one of the hand-levers through the intermediation of a push-and-pull rod. The cam-plate and push-and-pull rod can be seen at *a* and *b*, in Figs. 4 and 6. When the press is stopped for the insertion of a new blank, the crank-shaft will be standing with its cranks on the top centre, but the driving-shaft and spur-wheel will be running. The spring-controlled key will under these circumstances lie entirely inside the slot in the shaft. The moving of the cam-plate by the hand-levers, however, frees the key, so that it flies outward, under the action of a spring behind it, and engages with a notch in a hard-steel bush in the spur-wheel. As a result, the spur-wheel drives the crank-shaft and the press starts. When it has made a single stroke, the key will again slide out of gear, and the press will come to rest with its cranks on the top centre ready for the next stroke. Normally the press is stopped by the workman releasing the hand-levers after the blow has been given; but even if he holds the levers over, the press is still stopped by a knock-out gear, which is described below.

The double hand-lever mechanism is best shown in Figs. 4 and 5. The starting-lever proper is that which is operated by the workman's right hand, and which can be seen standing out from the right-hand end of the press at *c* in Fig. 4. This lever operates the push-and-pull rod, which works the clutch, through a bell-crank lever, shown at *d*, in Fig. 4. The lever is attached to the bell-crank lever by a link *e*. The vertical arm of the bell-crank lever engages an arm which projects from a boss *f* secured to the push-and-pull rod, as is best shown in Fig. 4. The operation of the arrangement will be clear. When the hand-lever is pressed down, it rotates the bell-crank lever, and—subject to the control of the second hand-lever described below—pulls the push-and-pull rod *d* longitudinally, so operating the clutch and starting the press. When a single stroke has been made, the hand-lever is released and falls back to its first position under the action of the weight shown in Figs. 4 and 5. At the same time the cam-plate of the clutch slides back, so that the clutch-key comes out of gear and the press stops with its cranks on the top centre, as before explained.

The second hand-lever, which has to be operated by the workman's left hand to start the press, is shown at *g*, in Figs. 4 and 5. As will be seen, it is pivoted to the frame near its top end, and at that end is formed into a ring which engages with the end of a horizontal rod *h*. The rod, which is arranged so that it can slide horizontally, carries the bell-crank lever *d* at its other end. The position of the rod is controlled by a spring, and matters are so arranged that when it is in its natural position the bell-crank lever lies in a different plane from the projecting arm on the boss *f*. As a consequence, if under these circumstances the hand-lever *c* is depressed, the upper arm of the bell-crank lever misses the projecting arm on the boss *f*, and the starting-clutch is not operated. To start the press it is necessary that the workman should first bring the bell-crank lever *d* into the correct position by operating the lever *g*. Still holding this lever with his left hand, he has then to operate the hand-lever *c* with his right hand. As a consequence, both his hands are occupied, and it is impossible for one of them to be left in a dangerous position on the table of the press.

There is yet another feature in this starting-gear to which attention should be directed. As has already been referred to, the movement of the press is confined to a series of individual strokes, the action being necessary for the cutting out and forming for which it is intended. Normally, as before explained, the workman releases the hand-levers after the moving slide has made a blow. If, however, he fails to do this, the press is still stopped by the action of a striking-peg which is carried by the brake-disc *k*. This brake-disc is mounted on, and rotates with, the crank-shaft. When the press has made a stroke and the slide is just completing its upward movement, the striking-peg occupies such a position that if the starting levers are still being held in the starting position, the peg strikes a second projecting arm on the boss *f*. This boss is free to rotate, and, as a consequence, as the striking-peg comes in contact with it the boss is moved round, and the first projecting arm comes out of engagement with the bell-crank lever *d*. As a result the push-and-pull rod *b* is released, the clutch *a* comes out of gear, and the press stops. It cannot be started again until the workman has brought the two hand-levers back to the "off" position and re-engaged the bell-crank lever with the first arm of the boss *f*. The brake-disc *k*, in addition to carrying the striking-peg, acts as a continuous brake and prevents the press running away. It ensures that it shall always instantly stop with the cranks on the top centre when the clutch *a* comes out of gear.

The driving-pulley of the press is 38 in. in diameter and has a 6-in. face. The mean power required is about 10 horse-power; but for individual motor drive a 20-horse-power motor is recommended.

CUTTING-OUT AND FORMING PRESS.

CONSTRUCTED BY MESSRS. TAYLOR AND CHALLEN, LIMITED, BIRMINGHAM.

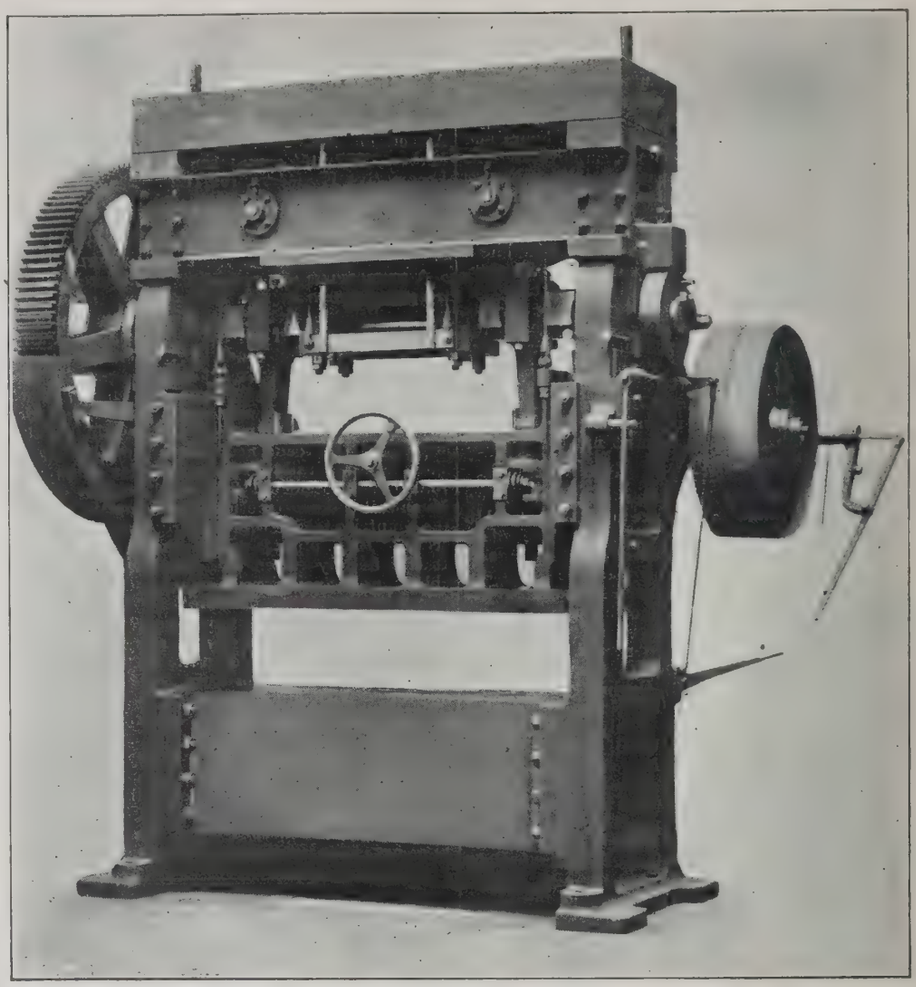


FIG. 1. GENERAL VIEW OF PRESS.

200-TON CUTTING-OUT AND FORMING PRESS.

CONSTRUCTED BY MESSRS. TAYLOR AND CHALLEN, LIMITED, ENGINEERS, BIRMINGHAM.

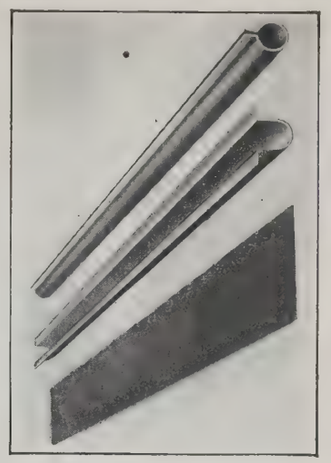

FIG. 9. EXAMPLE OF WORK DONE BY PRESS.

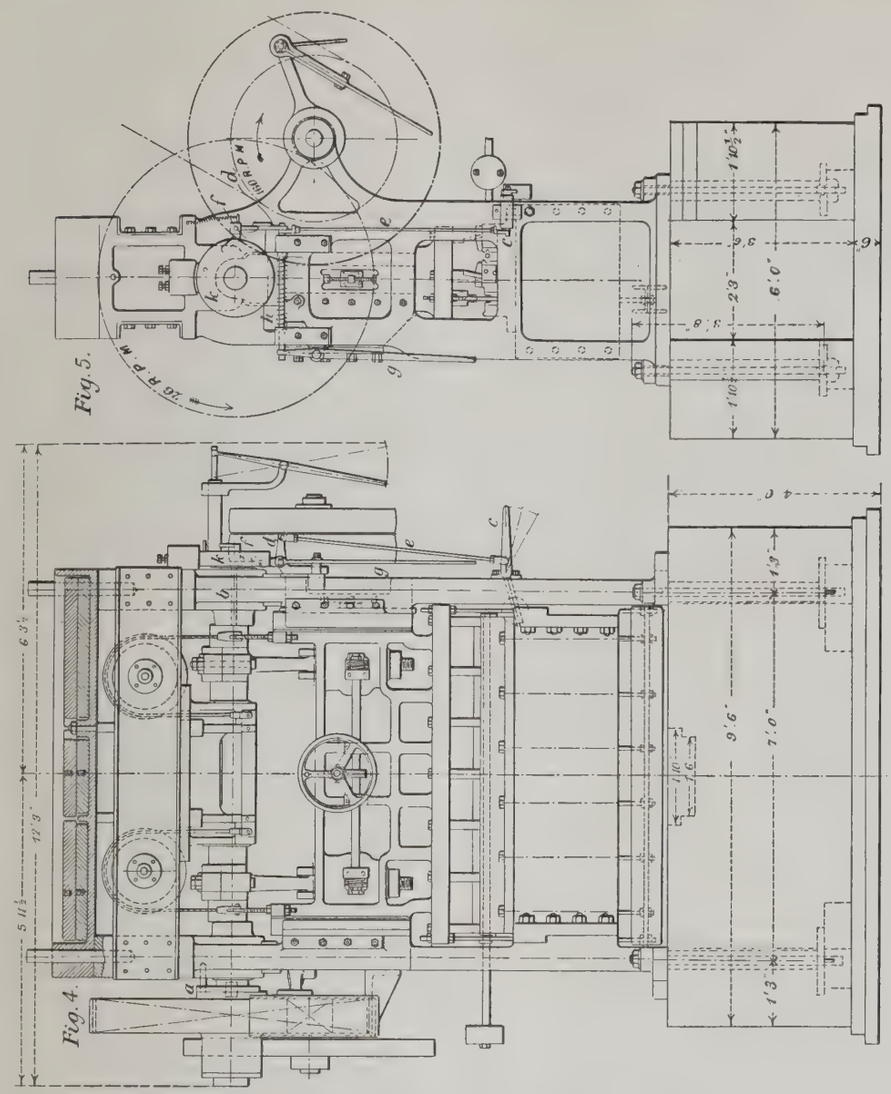

Fig. 5.

Fig. 4.

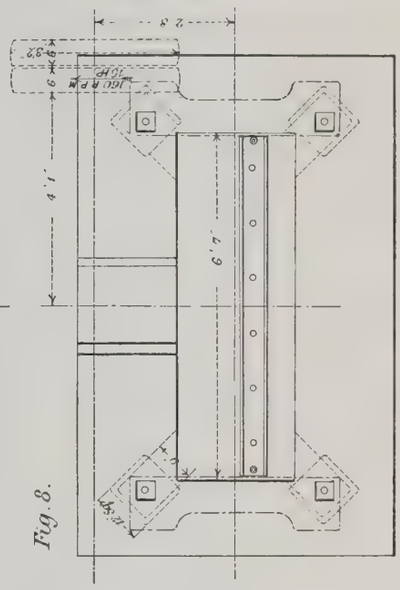

Fig. 8.

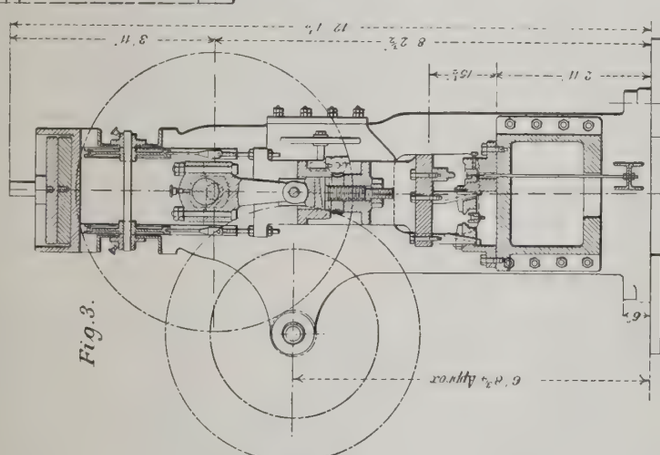

Fig. 3.

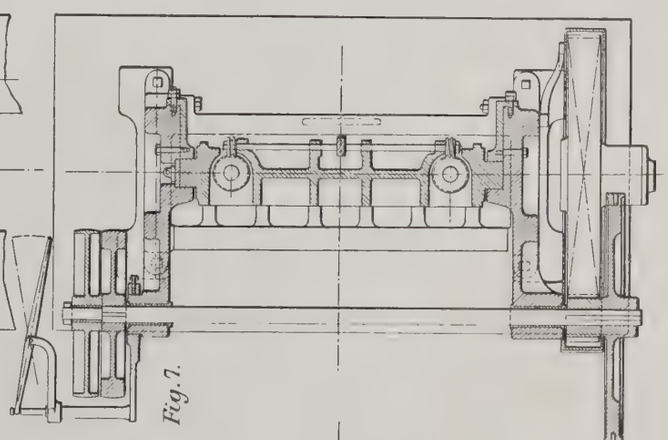

Fig. 7.

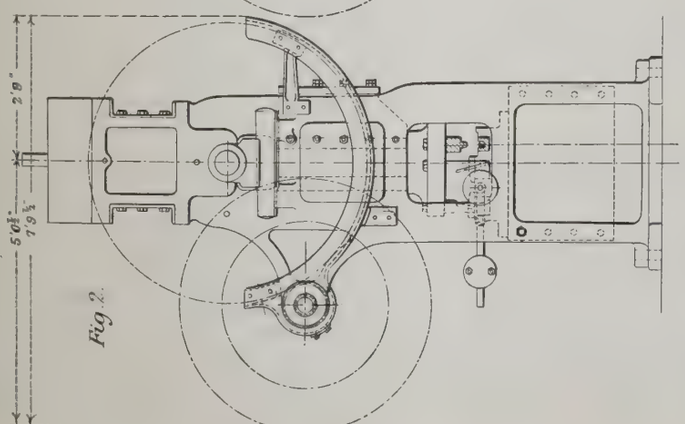

Fig. 2.

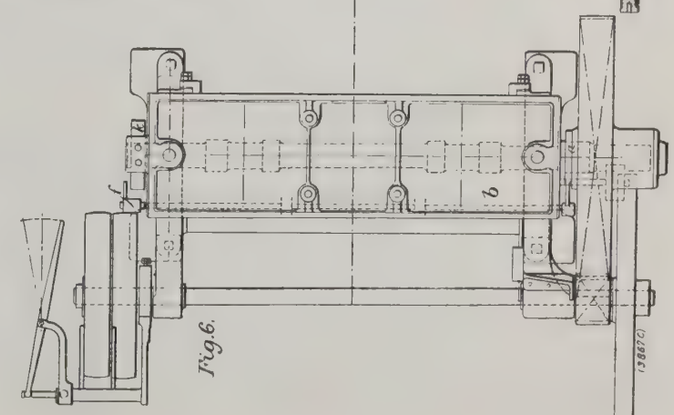

Fig. 6.

The stroke of the slide is 4 in., and the maximum vertical height between the bed and slide 15½ in. The bed is 6 ft. 6 in. wide between the side frames, and there are openings 18 in. wide in the frames to allow of work being passed endwise through the machine. The press is capable of exerting a pressure of 200 tons, and has a total weight of 18½ tons. It has a total height of 12 ft. 2 in., and occupies a floor space of 12 ft. 3 in. by 7 ft. 10 in.

The patent flanged tubes, shown in three stages of formation in Fig. 9, illustrates the class of work the machine is well fitted for. The piece of tube formed is 6 ft. long, so that it can easily be dealt with on the bed. It is formed in two operations, the two sets of tools being set up side by side in the machine. The strip is fed in from the front, and is formed in the first dies to the ∪ shape shown in Fig. 9. It is then passed on to the second set of dies, and the 1½-in. tube is completed. It is then removed endwise through the hole in the side frame of the machine. The material of the tube is 16 S.W.G. The dies that are used in forming it are shown in position on the machine in Figs. 2 to 5. The dies for the first process, in which the ∪ shape is formed, are well shown to the right in Fig. 3. The form and purpose of the male and female dies themselves will be obvious from the figure, and require no comment. Attention may, however, be directed to the ejector arrangement, by which the formed ∪ shape is expelled from the lower die. This consists of a series of six ejector-studs, which are operated by six vertical rods attached to a girder carried below the table. The girder is attached to the machine-slide by two long studs, and moves up and down with it. The arrangement is clearly shown in Figs. 3 and 4. The finishing dies are shown to the left in Fig. 3 and in some of the other figures. The tube is closed round a rod which lies over the lower die and below the upper die. The rod is not shown in Fig. 3, but is indicated in Fig. 5. It is secured at the left-hand end of the machine to a balanced lever, as shown in Fig. 2, and is also balanced longitudinally by a weight fixed to the projecting end, as shown in Fig. 4. These arrangements allow the rod to be swung upwards out of the way when the partially-formed blank is being moved from the first set of dies to the second. When the tube is completed it is removed endwise through the frame of the press, as before explained.

FERRO-CONCRETE ARCHED BRIDGE OVER THE GUMTI RIVER AT LUCKNOW, INDIA.

AN interesting example of the use of ferro-concrete in bridge construction is afforded by the new bridge over the River Gumti at Lucknow, which was recently opened by His Excellency the Viceroy, This structure, illustrated on page 124, replaces the Newabi Bridge at the Machli Bawan, which was built in 1780 by Asafud-dowlah, Nawab Wazir of Oudh.

The old bridge was constructed of nickunk in lime, and consisted of twelve small spans, with a centre span of 50 ft. Some ten years ago the piers showed signs of settlement, and the arch of the centre span cracked badly; as all attempts to deal with the settlement of the piers were ineffectual, it was decided to demolish it, and it was removed in 1907. The old bridge crossed the river at a considerable angle, and as it was considered useless to attempt to deal with and use any of the original piers, a site for the new bridge was selected some 100 yards up-stream, where the diverted roadway crosses the river at right angles, and provides a direct approach to the newly-completed King George's Medical College and Hospital.

The preliminary design for the new structure was prepared by Major Crookshank, R.E., and included five spans of 75 ft., the piers being 84 ft. from centre to centre. The preliminary estimate for this bridge in brickwork in lime amounted to 155,300 rupees (10,353*l.*). The detailed estimate was prepared in the chief engineer's office, and owing to slight alterations in the design was slightly increased to 158,000 rupees (10,533*l.*), and work on the foundations was commenced in 1910

Each pier is founded on three circular cylinders, which are carried down to the hard kunkar-clay layer at a depth of about 33 ft. below the river bed. The foundations for the abutments consist of three pairs of octagonal cylinders, also carried down to the kunkar-clay level.

The pier foundations are 14 ft. in width, and the piers and abutments are carried up to 15 ft. above the foundations. The level of the springing of the arches is at ordinary flood level, which is, however, 10 ft. below the level recorded during the extraordinary flood of 1904—the highest ever recorded at Lucknow.

At the breaking of the monsoon in 1912 the foundations had been completed and all the piers and abutments brought up to springing level. It was then decided to redesign the superstructure and to replace the heavy brick arches by reinforced-concrete ribs. The alteration in design was entrusted to Mr. A. C. Verrieres, C.I.E., and a revised estimate for 280,850 rupees (18,723*l.*) was sanctioned by the Government. The original elevation was adhered to, but the weight on the piers was considerably reduced by the substitution of seven concrete ribs in each span in place of the solid masonry arches.

The construction of the ribs will be understood from a reference to the engravings on page 124. Each rib is 2 ft. thick and 2 ft. 6 in. deep at the crown, and 6 ft. 6 in. on the springing face. Each rib is reinforced with eight 1¼-in. square steel bars, four at the upper and four at the lower edge, connected by stirrup-bars of ½-in. round steel. The proportions of the concrete were 1 part of Portland cement to 2 parts of red sand from the Jumna Valley, and 4 parts of crushed stone.

The centering for the two spans on the north side was formed of solid sand, as the river-bed was dry on that side during the period of construction. The sand being formed to the rise of the arch, a single layer of brick in mud was laid on the sand to the actual radius of the under side of the ribs. The channel of the river had formed under the second arch from the south end of the bridge, and for the centering of this span rows of salwood piles were driven, and a superstructure erected on these, formed of braced and framed struts, with a floor of sleepers to receive the ribs. The centering for the remaining two spans on each side of the channel was formed by filling the space between the piers with earth and sand up to springing level. Upon these earth-beds pillars were constructed in rough brick and mud to carry the wooden shuttering of the ribs.

The construction of the ribs proceeded simultaneously in all the spans during the hot weather of 1913, and the last rib was completed on July 28.

The main ribs are tied together by vertical cross-girders of ferro concrete, 9 in. thick, and varying in depth from 2 ft. 6 in. to 5 ft. These are reinforced by ½-in. steel rods. There are eight cross-girders in each span, and they are placed immediately beneath the spandrels.

The whole of the superstructure above the arches is of brickwork in lime, with red sandstone facings. The decking for the roadway is carried on jack-arches springing from steel joists resting on the spandrel pillars. The roadway is 22 ft. in width, with a 6-ft. footpath on each side.

It will be seen from the perspective view (Fig. 1) that a considerable amount of ornamental work has been added to the superstructure. This has been done in order that the design of the bridge may harmonise with the adjacent buildings of the Medical College and Hospital.

Mirzapur stone has been used to a considerable extent in the construction of the kiosks, minarets, and balustrading of the bridge, while ornamental iron brackets on each kiosk have been fitted with 100-candle-power electric lamps, supplied with current from the power-house at the Medical College.

The total cost of the bridge was 282,548 rupees (18,836*l.*), which only slightly exceeds the revised estimate for the work. In comparing the cost of the bridge having ferro-concrete ribs with the first estimate, which contemplated the adoption of brick arches, it must be borne in mind that in the Gangetic Plain the cost of brickwork is exceptionally low, owing to the cheapness of labour and the general availability of brick earth and native kunkar lime (ordinary straight brickwork costs usually 7 to 8 rupees (10s.) per cubic yard); while the cost of ferro-concrete is correspondingly high, owing to the scarcity of timber for centering and the high cost of Portland cement of good quality, which averages 5*l.* 5s. per ton imported and delivered at a distance from the coast.

The steel rods used in the construction of the Lucknow bridge were manufactured in India by the Tata Iron and Steel Company.

The whole of the work of design and construction of the bridge was carried out by the Indian Public Works Department, the officers employed on the reinforced-concrete superstructure being Mr. E. J. Powell, superintending engineer, and Captain J. A. Graeme, R.E., executive engineer, Medical College Division, under Mr. W. Gunnell Wood, chief engineer to the Government Roads and Rivers Branch.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.—This Association has issued the programme of the visit of members to l'Association Française pour l'Avancement des Sciences. A congress is to be held at Havre from Monday, July 27, to Sunday, August 2, 1914. The programme includes addresses by M. Jules Siegfried, Député, Président du Comité Local; M. Armand Gautier, Membre de l'Institut, Président de l'Association Française; Sir William Ramsay, K.C.B., F.R.S., Membre Etranger de l'Institut et de l'Academie de Médecine, Past President and Representative of the British Association; M. Perrot, Professeur à l'Ecole de Pharmacie de Paris, Secrétaire; and M. Perquel, Trésorier de l'Association Française. Various conferences and visits to places of interest have been arranged. Full particulars can be obtained from Mr. O. J. R. Howarth, Assistant Secretary of the British Association, Burlington House, London, W.

NOTES FROM THE NORTH.

GLASGOW, Wednesday.

Glasgow Pig-Iron Market.—Last Thursday morning the pig-iron market was dead idle, and no transactions were recorded. Cleveland warrants were quoted by sellers at 51s. 6d. cash and 51s. 8d. one and three months. The afternoon session was also idle, and Cleveland warrants were easier, with sellers quoting 51s. 4½d. cash, 51s. 6½d. one month, and 51s. 7d. three months. On Friday morning the market was steady, but once again there was little doing, as buyers were absent. The holiday feeling prevailed, and no dealing took place, and closing sellers quoted Cleveland warrants at 51s. 4½d. cash, 51s. 6½d. one month, and 51s. 7½d. three months. The market was closed in the afternoon for the annual Fair holidays, and remained so until Tuesday morning. When business was resumed the market was nominally steady, but idleness again prevailed. Sellers of Cleveland warrants quoted 51s. 5d. cash, 51s. 7d. one month, and 51s. 7½d. three months. In the afternoon business was again at a standstill, and quotations for Cleveland warrants were the turn weaker, with sellers naming 51s. 4½d. cash, 51s. 6d. one month, and 51s. 7d. three months. The market opened to-day (Wednesday) with a fairly steady tone, and one lot of Cleveland warrants changed hands at 51s. 4½d. cash, and closing sellers quoted 51s. 5d. cash, 51s. 6½d. one month, and 51s. 7d. three months. The afternoon session was a blank as regards business, but the tone remained steady, and sellers of Cleveland warrants quoted 51s. 5d. cash, 51s. 6½d. one month, and 51s. 7d. three months.

Sulphate of Ammonia.—No change of any kind has taken place in the sulphate of ammonia market during the past week, and prices are steady, the current quotations being 11*l.* per ton, Glasgow, and 11*l.* 2s. 6d. per ton, Leith, both for prompt lots.

Scotch Steel Trade.—The Scotch steel trade is quite idle at present, owing to the holidays, the weather for which has really been splendid, over the West of Scotland, at any rate. Not only does silence reign supreme in the works, but the selling departments are also very quiet, as little is being done in the way of booking new business. Inquiries are scarce, and contracts on offer are being largely snapped up by the agents for foreign manufacturers, at prices which local makers cannot look at. The holiday notices in some of the establishments intimate that work will be resumed on Monday next, but a restart then is rather doubtful owing to the unsettled state of the coal industry, and from the prevailing conditions it looks as if Monday week would be the more general date. The export trade is dull, and those lots which are being secured here are mainly for consumers who have a special preference for the Scotch article; even at the best the tonnage is not heavy. Prices are steady. The half-year has been a poor one, and the prospects for the second part of the year are far from bright.

Malleable-Iron Trade.—Since the various malleable-iron works closed for the holidays there has been very little inquiry, and also very little fixing up of new business. The foreign competition has told heavily on the local makers, and the past half-year's work will not show up too well.

Scotch Pig-Iron Trade.—Although there are actually no very visible signs of improvement in the Scotch pig-iron trade, some hold that the outlook is not so clouded as the majority make it appear. The threatened fight in the coal industry gives little cheer, and, despite that, prices have certainly an easier tendency when anything decent presents itself. The following are the market quotations for makers' (No. 1) iron:—Clyde, 66s.; Calder, Gartsherrie, Summerlee, and Langloan, 66s. 6d. (all shipped at Glasgow); Glengarnock (at Ardrossan), 70s.; Shotts (at Leith), 66s. 6d.; and Carron (at Grangemouth), 67s.

TRADE.—The Wolseley Tool and Motor-Car Company, Limited, announce that the name of the company has been changed to Wolseley Motors, Limited.

THE "BULLETIN OF THE IMPERIAL INSTITUTE."—The current quarterly issue of the "Bulletin of the Imperial Institute" (No. 2 of 1914) contains, among the reports of recent investigations by the scientific and technical staff, the results of examination of samples of soils from Nyasaland, of penguin guano from the Falkland Islands, and of flax from the East Africa Protectorate, where, it is thought, there is every prospect of the cultivation of this fibre becoming established in Nyanza Province. Other reports relate to cocoa from Nigeria, copals from British West Africa, essential oils from various countries, and cohune nuts from British Honduras. A special article by Mr. W. Small, M.A., B.Sc., Botanist of the Department of Agriculture, Uganda, deals with coffee cultivation in Uganda. It appears that coffee is now the staple crop of European planters in Uganda. The area is being extended, and a large increase in the exports of coffee may be looked for in the next few years. An article on "The Utilisation of Fish and Marine Animals as Sources of Oil and Manure" (Part I., Oils), discusses the composition and uses of fish oils, their sources and preparation, and also describes the present position of the whaling industry. Fur farming in Canada and the tin resources of Malaya and India are dealt with. It is interesting to note that considerably more than half of the world's supply of tin is produced within the British Empire; the output in 1911, the latest year for which final figures are obtainable, was: British Empire, 60,497 tons; foreign countries, 54,051 tons.

NOTES FROM SOUTH YORKSHIRE.

SHEFFIELD, Wednesday.

South Yorkshire Coal Trade.—The hard-steam market is showing a stronger tendency. Shipments are on a substantially larger scale, and a heavy tonnage is going into consumption in the armament works and in the general engineering trades. The only sign of weakness is in the demand from the lighter trades, where quietude reigns following a period of pressure. Collieries occupy a strong position, though forward business is not being arranged with the freedom that might be expected, seeing that small concessions are being offered on last year's contract rates. A moderate trade is passing in house coal. Though greatly restricted, the output is quite sufficient to meet a slow demand from the South Yorkshire district and from the South. Prices are still on the easy side. A fair tonnage of gas fuels has been despatched, chiefly on works contract account. Slacks are steadier. Weakness in the Lancashire demand is not so conspicuous. Coke sags. The extent of over-production is still great. Quotations:—Best branch hand-picked, 15s. to 16s.; Barnsley best Silkstone, 12s. to 13s.; Derbyshire best brights, 11s. 6d. to 12s. 6d.; Derbyshire house, 10s. 6d. to 11s. 6d.; best large nuts, 10s. 3d. to 11s. 3d.; small nuts, 9s. to 10s.; Yorkshire hards, 11s. to 12s.; Derbyshire hards, 10s. to 11s.; best slacks, 7s. to 8s.; seconds, 5s. to 6s.; smalls, 2s. 6d. to 3s. 6d.

Iron and Steel.—A period of marked stagnation in the raw material market has been followed by brisk buying of spot lots and some little inquiry on contract account. A few contracts have been arranged, but they are at exceptionally low figures, and only cover a brief period of delivery. In view of the low state of stocks, makers are hopeful of a revival in prices at any moment, and with this in view they are not disposed to accept long-dated contracts at rates which are only barely remunerative. That consumers are not at all perturbed by what the immediate future will bring forth is shown by the way in which they are allowing substantial contracts which will involve many months work to go uncovered. Foundry iron is by far the brightest medium. Reaction in forge qualities has continued for so long that a slight improvement is hardly noticeable. A fair tonnage of hematite is being delivered at the big steel-making and engineering works. For special qualities the demand is good. Bar iron does not make much headway. The South Yorkshire Makers' Association has decided to retain the basis quotation of 7*l.* 5s. A big quantity of foreign material is going into local consumption for the manufacture of cheap finished goods, for which purpose makers declare that the price of locally-produced semi-finished material renders its use prohibitive. Though seriously affected by the heat, the steel output does not fall far short of the average for this time of the year. But for a diminution in export requirements there would be little difference from the position which obtained in the recent "boom" period. Not only with the United States, but with Japan, British India, and Canada are exports seriously down. Comparing the net returns for the quarter just ended with the gross figures for the corresponding period in 1913, the total decline in exports from Sheffield to the United States was 57,512*l.* The chief cause of this decline was the shrinkage in steel exports, which fell from 166,788*l.* to 126,225*l.*, a decrease of over 40,000*l.* Declines were also shown in shears and edge and other tools. The heavy engineering trades are well employed and have a hopeful outlook. Railway steel is being made for South America and for Australia. Several big contracts on home railway and tramway account are in hand, including points and crossings for Doncaster and a heavy tonnage of axle forgings for London. Firms engaged in the production of munitions of war are as busy as ever. It is stated that Messrs. Vickers, Limited, have secured an order for the supply to a foreign Power of 300 garrison artillery guns of 6-in. calibre. Activity in the lighter trades is not so pronounced. Makers of agricultural tools are experiencing a fair season. Business in alloys and steel billets is quiet.

CONTRACTS.—We are informed that the Sirius Autogenous Works Company, Stratford, London, E., have secured the order from the Schmidt's Superheating Company, Limited, for a complete oxy-acetylene welding plant for their new works at Trafford Park, Manchester. The plant is of the same capacity as that recently supplied by the Sirius Company to the British Westinghouse Electrical and Manufacturing Company, Limited, Manchester. These plants will be the two largest automatic acetylene generators in this country.—Messrs. Stothert and Pitt, Limited, Bath, have just received an order from the Hull Joint Dock Committee for twelve electric cranes, and also a further order for four cranes for a new wharf on the Medway. All these cranes are fitted with their new "Toplis" patent horizontal luffing gear.

BRITISH COAL EXPORTS.—The exports of coal from the United Kingdom in the first half of this year—the expression "coal" including coke and patent fuel—amounted to 36,146,907 tons, and when to this is added coal shipped for the use of steamers engaged in foreign trade, the aggregate for six months becomes 46,329,064 tons. Coal has accordingly been leaving our shores this year at the rate of 92,658,128 tons per annum. The corresponding movement in the corresponding period of 1913 was at the rate of 94,270,348 tons per annum, and in the corresponding period of 1912 at the rate of 70,445,222 tons per annum. The principal exports to June 30, this year, were:—Russia, 2,009,789 tons; Sweden, 1,800,093 tons; Norway, 1,247,501 tons; Denmark, 1,389,551 tons; Germany, 4,202,651 tons; France, 6,818,125 tons; Spain, 1,756,681 tons; Italy, 4,533,077 tons; Egypt, 1,636,842 tons; and the Argentine Republic, 1,825,940 tons.

NOTES FROM CLEVELAND AND THE NORTHERN COUNTIES.

MIDDLESBROUGH, Wednesday.

The Cleveland Iron Trade.—The slight improvement manifested in the inquiry for pig-iron during the week has steadied quotations. Though the orders have not been for large quantities, they have served to lend hopefulness to the sellers' outlook, notwithstanding that the present output of iron is not being absorbed by current requirements. The quotations for Cleveland warrants are 51s. 3½d. cash buyers, and 51s. 4½d. to 51s. 5d. sellers. No. 3 g.m.b. realises 51s. 6d. per ton; No. 1 is 53s 6d.; foundry No. 4 is 51s. 3d.; and forge No. 4 is 50s. 9d. per ton. There is not a great deal doing in hematite, which is maintained at 59s. per ton. For Rubio ore, 50 per cent. quality, 17s. is the prevailing quotation. Blast-furnace coke is 17s. 6d., medium quality, delivered at Tees-side furnaces.

Iron Trade Statistics.—The quarterly returns of the Middlesbrough Chamber of Commerce, issued this week, show that at June 30 last there were within the port of Middlesbrough 50 blast-furnaces in operation, out of 77 built, as compared with 60 in blast and 77 built for the second quarter of a year ago. During the past three months the production of pig-iron in Middlesbrough was 595,000 tons, 355,000 tons of which was Cleveland iron, and 240,000 tons hematite, spiegel, basic, and other special irons. For the previous quarter the output was 630,000 tons, of which 330,000 tons was Cleveland, and 300,000 tons hematite, &c.; for the second quarter of a year ago the make was 715,000 tons, 415,000 tons being Cleveland, and 300,000 tons hematite, &c. The total output of pig-iron for the half-year amounted to 1,225,000 tons, of which 685,000 tons were Cleveland, and 540,000 tons hematite, &c. Shipments of pig-iron from the port of Middlesbrough during the first six months totalled 546,940 tons, against 527,826 tons in the same period last year. The imports of foreign ore into Middlesbrough during the quarter reached 490,768 tons, as compared with 519,045 tons during the previous quarter and 608,749 tons during the second quarter of 1913. The total for the half-year was 1,009,813 tons, as compared with a total of 1,195,983 tons for the first half of 1913. The total value of goods other than coal and coke exported to foreign and Colonial destinations from Middlesbrough during the quarter was 2,730,720*l.*, a decrease of 645,241*l.* on the previous quarter.

Stocks and Shipments.—The stock of Cleveland pig-iron in the public warrant stores now stands at 81,426 tons, all of which is No. 3 quality. Since the beginning of the month the stock has been increased by 3137 tons. Shipments of pig-iron from the Tees are on only a moderate scale. To date this month they average 2182 tons per working day, the total despatches being returned at 41,475 tons, 37,092 tons of which have gone from Middlesbrough, and 4383 tons from Skinningrove. To the same date last month the loadings were given at 49,988 tons, or a daily average of 2737 tons, and for the corresponding part of July, a year ago, the clearances reached 61,028 tons, or an average of 3212 tons per working day.

Manufactured Iron and Steel.—More encouraging accounts are given of the different branches of manufactured iron and steel trades. Specifications are coming in better. Inquiries for joists and constructional work are heavier, and prices for export are hardening. An order for 2000 tons of rails has been booked by the North-Eastern Steel Company for Southampton, at 6*l.* 18s. per ton, a German tender for 6*l.* 12s. being rejected. It is expected that orders for 58,000 tons of rails will be placed in this district shortly. Principal market quotations stand:—Common iron bars, 7*l.*; best bars, 7*l.* 7s. 6d.; best best bars, 7*l.* 15s.; packing iron, 5*l.* 5s.; iron ship-plates, 6*l.* 15s.; iron ship-angles, 7*l.*; iron ship-rivets, 7*l.* 5s.; iron girder plates, 7*l.* 5s.; steel bars (basic), 6*l.* 5s.; steel bars (Siemens), 6*l.* 5s.; steel ship-plates, 6*l.*; steel ship-angles, 5*l.* 15s.; steel boiler-plates, 7*l.*; steel joists, 6*l.* 12s. 6d.; steel strip, 6*l.* 5s.; steel hoops, 6*l.* 10s.—all less the customary 2½ per cent. discount; cast-iron columns, 7*l.* 7s. 6d.; cast-iron railway chairs, 4*l.* 5s.; light iron rails, 7*l.*; heavy steel rails, 5*l.* 15s. to 5*l.* 17s. 6d.; steel railway sleepers, 7*l.*—all net at works; galvanised corrugated sheets, No. 24 gauge, in bundles, 11*l.* f.o.b.—less 4 per cent.

MESSRS. HENRY HOLLINGDRAKE AND SON, LIMITED, STOCKPORT.—On Saturday, the 18th inst., this firm of ironfounders, brassfounders, engineers, and general mill furnishers celebrated its centenary. It came into existence just one hundred years ago, and has grown from a small foundry into a most modern concern, thoroughly well equipped for a number of different branches of manufacture.

AMERICAN RAILROADS.—The railroads of the United States, with annual traffic revenues exceeding 100,000 dols., comprised 242,657 miles of line last year, as compared with 238,220 miles in 1912. The traffic receipts in 1913 were 3,125,135,000 dols., as compared with 2,826,958,000 dols. in 1912. The working expenses in 1913 were 2,169,968,000 dols., as compared with 1,959,094,000 dols. in 1912. The number of passengers carried last year was 1,033,679,000, as compared with 994,372,000 in 1912. The quantity of freight carried was 2,058,035,000 tons, as compared with 1,818,795,000 tons. The number of locomotives owned was 63,375, as compared with 61,276; and the number of cars was 2,445,508, as compared with 2,368,942. The aggregate number of persons employed upon the lines last year was 1,815,239, as compared with 1,799,931. The average rate of dividend last year upon outstanding stocks was 4.28 per cent.

NOTES FROM THE SOUTH-WEST.

Cardiff.—Admiralty steam coal has been firm and scarce. Good secondary qualities have shown a tendency to harden for forward loading, but they have shown no improvement for prompt shipments. House coal has exhibited scarcely any change, and the same may be said of coke, patent fuel, and iron ore. The best Admiralty large has made 20s. 6d. to 22s.; best secondary descriptions have brought 18s. 6d. to 19s. 6d.; other secondary qualities, 17s. 3d. to 17s. 9d.; best bunker smalls, 20s. 3d. to 20s. 6d.; and cargo smalls, 7s. 6d. to 8s. 3d. per ton. The best household coal has been quoted at 19s. to 20s.; good households have made 17s. to 18s.; No. 3 Rhondda large has brought 17s. 6d. to 17s. 9d.; and smalls have been quoted at 12s. to 12s. 6d. per ton. No. 2 Rhondda large has realised 12s. to 13s.; and No. 2 smalls, 8s. to 8s. 6d. per ton. Special foundry coke has made 25s. to 29s.; good foundry coke, 20s. to 23s.; and furnace coke, 17s. to 19s. per ton. As regards iron ore, Rubio has been quoted at 16s. to 16s. 6d. per ton, upon a basis of 50 per cent. of iron, and charges, including freight, insurance, &c., to Cardiff or Newport.

More Welsh Coal.—Mr. A. W. Brown (at one time a working collier in the Forest of Dean) has struck a good workable seam in the Tranchard vein in the Crossways Iron Mine Gale. The seam is 2 ft. 2 in. in thickness.

Foreign Coal Contracts.—The Greek Government has placed orders for 35,000 tons of best Admiralty large, 30,000 tons through a London firm, and 5000 tons through a Cardiff house—deliveries to be made during the next two months. Tenders for 20,000 tons of bituminous smalls required for the Belgian State Railways have ranged between 11s. 3d. and 13s. 2d. per ton, according to the place of delivery. The tenders sent in amounted to 165,000 tons.

Gloucester Wagon Company.—The directors of the Gloucester Railway Carriage and Wagon Company, Limited, report that the profit on the past year's trading, after making provision for depreciation, was 80,133*l.* The disposable balance, after deducting an interim dividend paid in February, amounted to 69,995*l.* The directors propose to transfer 10,000*l.* to the reserve fund, which will then amount to 160,000*l.*, and they recommend a dividend for the past half-year at the rate of 10 per cent. per annum, making 10 per cent. for the year. A balance of 41,601*l.* is carried forward. The company now repairs and maintains 26,631 wagons.

THE MEUSE.—Works are contemplated for improving navigation on the Meuse. It is proposed to construct additional sluices, at an estimated cost of 160,000*l.* Four tenders for the works have been received; the lowest is that of Hottat and Sons, of Brussels (134,680*l.*).

HULL.—A scheme prepared by the Hull city engineer for a floating landing-stage at Corporation Pier, Hull, was submitted to Mr. A. C. Hurtzig, who has forwarded a report unfavourable to the project. A sub-committee had passed a resolution instructing the town clerk to forward Mr. Hurtzig's report to the general manager of the Great Central Railway, and to inquire whether he would be prepared, with the Great Central Company's engineer, to meet representatives of the Hull City Council in London at an early date to discuss a scheme for providing improved accommodation at the pier. The property committee of the Hull City Council has authorised the Hull city engineer to prepare a rough sketch showing how such improved accommodation could be provided.

GERMAN PIG-IRON PRODUCTION.—The production of pig in Germany and the Luxembourg in June amounted to 1,531,313 tons, as compared with 1,609,748 tons in June, 1913. The total of 1,531,313 tons was made up as follows:—Casting pig, 248,608 tons; Bessemer pig, 30,699 tons; Thomas pig, 1,021,623 tons; spiegel and steel pig, 192,753 tons; and puddling pig, 37,630 tons. The monthly production to June 30 this year compared as follows with the corresponding production in the corresponding period of 1913:—

Month.	1914. Tons	1913. Tons
January	1,566,505	1,611,345
February	1,445,511	1,493,877
March	1,602,896	1,629,463
April	1,534,429	1,588,701
May	1,607,211	1,643,069
June	1,531,313	1,609,748

The aggregate output to June 30, this year, was accordingly about 9,288,000 tons, as compared with 9,576,203 tons.

STEEL CAR PATENTS.—We are informed that a patent case of some importance has recently been decided in the United States, in the Court of Appeals of the District of Columbia. The patent in question was one filed in 1906 by Mr. W. R. McKeen, relating to the construction of steel box-cars. The first two box-cars built on the system involved were turned out from the Union Pacific shops in Omaha, 1906 and 1907. Since that date the patent has been contested before the Examiners-in-Chief, Commissioner of Patents, and the Court of Appeals, District of Columbia. The decisions settle the validity of the patent, which was therefore issued on June 19 last. The patent is for all-steel box-car construction. Such cars are rapidly coming into use in the United States, and are proving suitable to the requirements of modern traffic conditions. It may be pointed out, for instance, that while the wooden box-car is a constant source of annoyance in grain traffic, owing to leakage through parts damaged by severe service, the steel box-car will carry grain with practically no loss.

FERRO-CONCRETE ARCHED BRIDGE OVER THE GUMTI RIVER AT LUCKNOW.

MAJOR CROOKSHANK, R.E., AND MR. A. C. VERRIERES, C.I.E., ENGINEERS.

AGENTS FOR "ENGINEERING."

AUSTRALIA: Gordon and Gotch, Limited, Melbourne; Sydney; Brisbane; Perth. Turner and Henderson, Sydney, N.S.W. T. Willmett and Co., Townsville, North Queensland. W. C. Rigby, Adelaide, South Australia. Melville and Mullen, Melbourne, Victoria.
AUSTRIA-HUNGARY, Vienna: Lehmann and Wentzel, Kartnerstrasse.
BELGIUM: E. F. Satchell, 45, Avenue de Terneuzen, Brussels.
CANADA, Toronto, Ont.: Wm. Dawson and Sons, Manning Chambers. Montreal: Sells, Limited, 302 Shaugnessy Building, McGill-street.
EDINBURGH: John Menzies and Co., 12, Hanover-street.
FRANCE, Paris: Boyveau and Chevillet, 22, Rue de la Banque. For Subscriptions and Advertisements, Librairie B. Tignol, 53bis, Quai des Grands-Augustins, Paris. Also for Advertisements, Agence Havas, 8, Place de la Bourse.
GERMANY, Berlin: A. Asher and Co., 13, Unter den Linden. Leipzig: F. A. Brockhaus. Mulhouse: H. Stuckelberger.
GLASGOW: William Love.
INDIA, Calcutta: Thacker, Spink and Co. Bombay: Thacker and Co., Ltd.
ITALY: U. Hoepli, Milan, and any post-office.
LIVERPOOL: Mrs. Taylor, Landing Stages.
MANCHESTER: John Heywood, 143, Deansgate.
NEW ZEALAND: Gordon and Gotch Proprietary, Limited, Wellington, Auckland, and Christchurch.
NORWAY, Christiania: Cammermeyer's Boghandel, Carl Johans Gade, 41 and 43.
ROTTERDAM: H. A. Kramer and Son.
SOUTH AFRICA: Central News Agency, Limited, Head Office—Johannesburg; and Pretoria, Cape Town, Port Elizabeth, Bloemfontein, Durban, and their various branches and bookstalls throughout South Africa. Also Cape Town: Wm. Dawson and Sons, 31, Long-street.
TASMANIA: Gordon and Gotch Proprietary, Limited, Launceston; Hobart.
UNITED STATES, New York: W. H. Wiley, 432, Fourth Avenue. Chicago: H. V. Holmes, 957-958, Monadnock Block.

ADVERTISEMENT RATES.

The charge for advertisements is three shillings for the first four lines or under, and eightpence for each additional line. The line averages seven words. Payment must accompany all orders for single advertisements, otherwise their insertion cannot be guaranteed. Terms for displayed advertisements on the wrapper and on the inside pages may be obtained on application. The pages are 12 in. deep and 9 in. wide, divisible into four columns of 2¼ in. in width. Serial advertisements will be inserted with all practicable regularity, but absolute regularity cannot be guaranteed.

Advertisements intended for insertion in the current week's issue must be delivered not later than 5 p.m. on Thursday. In consequence of the necessity for going to press early with a portion of the edition, alterations for standing advertisements should be received not later than 1 p.m. on Tuesday in each week.

SUBSCRIPTIONS, HOME AND FOREIGN.

"ENGINEERING" can be supplied direct from the Publisher post free, for twelve months, at the following rates, payable in advance:—

For the United Kingdom	£1	9	2
For Canada—			
Thin paper copies	£1	11	6 ($7.65)
Thick ,, ...	£1	16	0 ($8.75)
For all other places abroad—			
Thin paper copies	£1	16	0
Thick ,, ...	£2	0	6

When foreign subscriptions are sent by Post-Office orders, advice should be sent to the Publisher.

Foreign and Colonial subscribers receiving incomplete copies through newsagents are requested to communicate the fact to the Publisher, together with the agent's name and address.

All accounts are payable to "ENGINEERING," LIMITED. Cheques should be crossed "Union of London and Smith's Bank, Limited, Charing Cross Branch." Post-Office Orders should be made payable at Bedford-street, Strand, W.C.

Offices for Publication and Advertisements, 35 and 36, Bedford-street, Strand, London, W.C.

We desire to call the attention of our readers to the fact that the above is our SOLE ADDRESS, and that no connection exists between this Journal and any other publications bearing somewhat similar titles.

TELEGRAPHIC ADDRESS } "ENGINEERING," WESTRAND, LONDON.

TELEPHONE NUMBERS—3663 and 8598 GERRARD.

READING-CASES.—Reading-cases which will hold twenty-six numbers of "ENGINEERING" may be had of the Publisher or of any newsagent. Price 6s. each.

NOTICE.

Immediately following the Index to our last volume, which is published with the current issue, will be found a Classified Directory of Current Advertisements in ENGINEERING, together with a List of the Telegraphic Addresses of the Advertisers and Key. This Directory and List with Telephone Numbers and Telegraph Codes in use, together with Glossaries for the use of Foreign Buyers, is also published in compact book form for handy reference, and may be had gratuitously on application to the Publisher. This Directory is sent at regular intervals to the principal purchasers of machinery throughout the world.

ENGINEERING.

FRIDAY, JULY 24, 1914.

EFFECTS OF SHORTER WORKING HOURS.

IN no recent labour dispute has the influence of trade-union methods on national industry been so clearly illustrated as in that which threatens a complete stoppage of work by all miners in Scotland, if not throughout the United Kingdom. There is practically no justification for the attitude of the Scottish miners, whether consideration is given to its effect upon the men themselves, upon trade unions generally, or upon national interests. Miners' wages have, in many cases, for a long time been determined on a sliding scale with reference to the prevailing prices of coal, and the present wage in Scotland, which is 7s. per day, is 75 per cent. above the rates of pay in 1888. Decreased activity in practically every industry has involved, or threatens to involve, a lessened demand for coal, with the result that prices are diminishing, and there is great probability that the rates of pay will decrease. The miners of Scotland therefore took the extreme step of arranging that instead of working for 5 or 5½ days a week, as at present, they—or at least a large proportion of them—would adopt a four-day week, with the avowed object of so restricting the production of coal as to bring about an increase in the average selling price. In fulfilment of this policy it was proposed that Monday next should be an idle day; but the owners decided that if the men abstained from work on Monday, all the miners in Scotland would be locked out. The men asked the Miners' Federation of Great Britain, in such event, to declare a national strike, and this request was considered at a special conference at Southport last Tuesday and Wednesday. The Federation, however—although their president also occupies a similar position in the Scottish Federation—did not seem disposed either to agree to a general strike or formally to support the miners of Scotland in their demands. On the other hand, the Scottish Federation have decided, obviously as a result of this week's meeting in Southport, to abandon the four days per week programme. Should wages be reduced by the Conciliation Board under 7s. per day, the Scottish miners are authorised to strike immediately, and a ballot is to be taken of the whole country on the question of a national stoppage in support of the men in the North. It seems improbable that such a stoppage will be agreed to, and, in any case, the Scottish miners have no definite guarantee of immediate assistance.

This brief statement of the case might pass without further comment, because it carries with it condemnation of the policy of the workers of the North. It is, however, so characteristic an example of the general trend of trade-union reasoning that some further reference may be made to it, in the hope that light may be thrown upon the untenable attitude now assumed much too frequently. We have said that the policy is ruinous for the workers concerned. The chairman of the Scottish Federation contends that if the wage falls below 7s. per day it would be "nearly impossible for miners to live decently." The best commentary on this is that the average time worked per week at present is five days, giving 35s. per week, whereas the full time would be six days, rendering possible a weekly wage of 42s. At the present time the men must be living decently on a wage considerably less than 7s. per day, otherwise they would work the full week. Moreover, the proposed restriction of the days of labour to four per week would have brought the average remuneration down to 28s. This, too, would have given the workers three days per week of leisure, and idleness in such circumstances involves more expenditure to "kill time."

We have at all opportune times contended for liberal remuneration for labour, but this in itself, in the national interest, requires high industrial efficiency. Leaving aside for the moment the question whether short time or the artificial restriction of output in any country can be efficacious in maintaining a higher average price for a product such as coal, it must be recognised that the amount of wage which can be paid to workers is in a large measure dependent upon the efficiency of the plant. The cost of production, and therefore the profitable selling price of a commodity, is dependent upon three factors. The first, in point of importance, is the efficiency of the mechanism placed in the hands of the worker; the second is the continuity with which the workers use this plant, and, consequently, the volume of the product per unit of time and of labour cost; and the third is the success of the management, not only in the working of the mine, but in the disposal of the products in keenly-contested markets. If 10,000*l.* be paid over by the workers, the capitalist, the community, or even by Syndicalists, for the installation of mechanical appliances to assist manual labour in the process of production, a return on this money must be found, and the greater the volume of output per unit of time the easier will it be to afford a high wage for the worker, in addition to an adequate return upon the money invested. If, on the other hand, 10,000*l.* worth of machinery is utilised for four days per week instead of six days per week, with a consequent diminution of the tonnage, say of coal produced from a mine, 33 per cent. greater charge must be made against each ton of coal to provide on-cost charges and the same return on the 10,000*l.*, in addition to the satisfactory wage. Herein lies the crux of the question of economy in production. Shortening of hours must increase the cost of production, and consequently cannot conceivably, in a competitive market, gain for the workers a higher rate of wage. This argument applies to all workers in every factory. Instead of the wages varying with the selling price, according to the present application of the sliding scale, we should prefer to see them vary with the amount of time worked by each operative. The man who works six days per week is, other things being equal, more efficient than he who works only four or five days per week, because he enables a higher output to be obtained from the mechanical appliances at his disposal and enables the incidental permanent charges to be spread over a wider field. If the arrangement were not too complicated, we should like to see the sixth day of a man's weekly work paid at a higher rate than the fifth day.

Memory is short, and the workers of one generation never accept the experience of their predecessors. It is an axiom that experience which is not directly expensive is seldom fully appreciated. In 1894 the Scottish miners struck work and appealed to their co-workers in England for assistance in the belief that if their object were attained those of the south would profit. The southerners profited because they continued at work producing coal which found its way to Scotland. At the same time they refused to make a formal strike allowance. The voluntary contributions worked out at a trifle over 1s. per man per week to those concerned in the Scottish strike Mr. R. Chisholm Robertson, a past-president of the Scottish Miners' Federation, brings back to memory at the present juncture this salient lesson; he points out that the movement in Scotland now has been forced a long way along the road of disaster without any definite arrangement with the Miners' Federation of Great Britain to ensure co-operation or a definite scheme of help. Indeed, he goes further, and predicts that history will repeat itself. He says that, "as in 1894, the miners of England and Wales will continue to work, take full advantage of the markets of the Scottish coal suppliers, give voluntary doles—not full lock-out allowances—the Scottish general public will be put to inconvenience and loss, and in suffering and disaster the Scottish miners will be given another cruel lesson of the value of disregarding the teaching of dire experience." Similar language might be used in practically every strike. Mr. Chisholm Robertson himself enforces the point. "If the Scottish miners had a monopoly of the home and foreign markets, they could, by restriction of output, raise prices to a high level—to a level determined by the necessity of general producers and consumers. To the extent that they have not a monopoly of supplying coal, the restriction must be abortive and, both imme-

diately and in the future, be hurtful to their interests." As it is, ships are deserting the Clyde ports in anticipation of the lock-out or strike, and are taking their supplies from the English and Welsh, and even the German, ports, for foreign markets. At the present time no country, not even Britain, can be said to have a monopoly in any branch of manufacture or production, and thus, when work is stopped, those seeking supplies necessarily look to other countries, whose workers profit by the cessation of production, partial or otherwise, in this country. Commercial relationship thus established under emergency conditions has the habit of becoming permanent, and consequently each strike closes many doors for the reception of the work of the producers on strike.

Not only the men, but unions thus suffer seriously. In the report of the Chief Registrar of Trade Unions for 1912, which has been issued this week, it is shown that the miners' strike of that year cost the miners' union over one million sterling, while other unions, in paying unemployment benefit, lost very heavily. The unions in the transportation group, for instance, paid out 125,000*l.*, or more than ten times as much as in the previous year; two of the railwaymen's unions, 100,000*l.*; and the engineering unions, 40,000*l.*, due entirely to this one strike. And yet it is doubtful if any advantage accrued even to the miners' union.

Even greater and more widespread effects always result to the nation from shorter hours. An effective example is that of the colliers, because coal is one of those products which is universally utilised, and any change in the price affects every citizen. The ostensible object of the Scottish coal-miners' action was to increase the selling price. If they had achieved their purpose, the loss would have fallen upon every citizen, either in his work or in his home. The loss, too, would have been immensely greater in its aggregate effect than any gain which the miner might have secured; because not only would the coal-winner have been paid an inflated wage, since he would have worked shorter time, but additional loss would have been involved owing to the mechanical appliances at the mine being idle over a considerably longer period per week. The user has to pay, as the maintenance of the selling price in Scotland at an artificial level would have minimised the influence of competition; coal imported from England or Germany would only have been sold at about, or slightly less than, the price demanded by the home producer. Again, as the increased charge for coal at every factory would have involved higher cost for steam power, the effect would have been to enhance the cost of production of all manufactures. In turn, this would have consequently added a handicap to Scotch producers in the competitive markets of the world, and would have resulted in less demand for labour in other industries. These are truisms well understood by all who take time for reflection, but the trade unionist of to-day is too prone to neglect the national interests, and therefore every opportunity should be utilised for enforcing these economic truisms.

FUEL-BRIQUETTING INVESTIGATIONS.

THE manufacture of fuel-briquettes is now well established as a commercial process on the Continent of Europe, and, so far as the demand permits, in Great Britain. But in the United States, in spite of the vast fields of lignite, or brown coal, which are available, the industry cannot be said to have attained a proper foothold. Up to 1912, in fact, there were only twenty-four American plants in operation. For this reason the Government arranged an exhaustive series of experiments on the briquetting of Americal fuels, and a mass of useful information has been collected. The results, which are given in great detail, are published in Bulletin No. 58 of the U.S.A. Bureau of Mines, and cover a period of eight years' work, from July, 1904, till July, 1912.

Briquettes are made by compressing the finely-ground material into solid blocks, under a sufficiently high pressure. The blocks, if made from lignite suitably treated, are then cohesive, withstand handling, and keep their shape in the fire. But with anthracite, bituminous, and sub-bituminous coals, and even with certain lignites, cohesive blocks cannot be made without the use of a suitable binding material to keep the particles together. More binding material is required with anthracite than with bituminous coals, but peat, like lignite, can be briquetted by pressure alone. The binder which has been most commonly in use up to now is pitch; but, unfortunately, briquettes made with this material are very smoky in burning. Hence many of the United States experiments have been devoted to discovering suitable substitutes. In this respect the chief difficulty which has been encountered is that smokeless binders are generally not waterproof, and can be made so only at a more or less prohibitive cost. As shown by the experiments, however, the difficulty is not an insurmountable one.

The use of briquettes, so far as anthracite and bituminous coals are concerned, lies in the utilisation of the fine or small coal. Although some fine coals coke when burning, most of them remain in their natural state, with the result that the dust clogs the draught, or falls through the bars with the ashes. Well-made briquettes, on the other hand, retain their form in the fire, and allow of a good air circulation being established. It follows that, where the difference in price between lump and fine coal is sufficient, they can be manufactured and sold at a profit. Other advantages which briquettes possess over ordinary coal are that they burn to a fine ash without clinker; the stoker's work is easier; the evaporative power, owing to the higher calorific value of the binder and the loss of moisture, is increased; more resistance is offered to the weather; and the risk of spontaneous combustion is eliminated.

In the case of lignite, which requires no binder, and in its natural state contains a high percentage of moisture, the advantage of briquetting requires no demonstration. A series of tests reported in the United States bulletin shows that, where the moisture content of the samples varied from 33 per cent. to 42 per cent., from 24 per cent. to 32 per cent. was removed in briquetting, and the heating value of the fuel was increased by from 36.5 per cent. to 52.4 per cent.

These experiments are of the highest importance to Americans, but, in view of the smallness of our lignite supplies, do not possess the same interest for us. The principal European lignite fields are located in Germany and Austria-Hungary. In this country, where chiefly bituminous and anthracite coals are produced, it is with the working up of the "smalls" of these coals that we are concerned. Our output is smaller in proportion than that of other European countries, for the reason that briquettes have not been adopted to any great extent in our locomotives and steamships.

The plant required for making briquettes from anthracite or sub-bituminous coals includes a coal-elevator, pitch-cracker, pitch-elevator, measurer, mixer, disintegrator, compo-elevator, vertical heater, briquetting-machine, and briquette-conveyor. The coal is fed into the elevator direct from the wagons, and the pitch, after going through the cracker, falls into the boot of the pitch-elevator. Both are then discharged into the mixer and measurer, which consists of two screw-conveyors—a large one for the coal, and a smaller one for the pitch. The pitch falls from the smaller conveyor on to the coal in the larger conveyor below, and so becomes mixed with it. The compo is then elevated and discharged into the vertical heater, which forms commonly a part of the briquetting-machine itself. In the heater the mixture is heated up, either by a steam-jacket or by the injection of live steam, preferably superheated, and is at the same time more intimately mixed by revolving beaters. The semi-plastic material is finally fed into the moulds of the briquetting-machine, which are arranged on either a vertical or horizontal table, and a system of levers press it from both sides into rectangular blocks, under a pressure of about 2 tons per square inch. Facilities are provided for filling and discharging the moulds, for giving a rotatory feed to the table, and for varying the pressure. For the smaller eggette or ovoid briquettes, which are now in many cases replacing those of rectangular shape, a different type of machine is used, and the moulds are formed in the peripheries of rollers, which press on tangential feed-slides. In the case of lignite and peat briquetting, the material is forced through a tapered tube in a continuous stream, and is cut off by a wire cutter into cylindrical briquettes of the required length. Portable plants for railway use have also been designed, and a typical example was described in ENGINEERING for April 3, 1914.

The English plant, by Messrs. William Johnson and Sons (Leeds), Limited, used in the American experiments, was substantially as above described, except that it was modified in several respects to meet the needs of the experimenters. The principal alteration made was in the measurement of the coal and binder. To ensure absolute accuracy, this was effected by the use of separate scales, instead of by differential conveyors. In the first American plant, by the Renfrow Briquet Machine Company, St. Louis, horizontal heating cylinders were used, fitted with worm-conveyors, instead of beaters. Otherwise the arrangement closely resembled that of the Johnson plant. But in the case of the second American machine, by the American Compressed Fuel Company, Chicago, a different design was adopted. After being measured, the coal was dumped into a steam-jacketed mixer, where the pitch, which had previously been melted and measured, was mixed with it. The mixture was then fed into a roller-press, and formed into briquettes of the eggette type.

For lignite, a German plant by the Maschinenfabrik Buckau Actien-Gesellschaft, of Magdeburg, was used. The lignite, before entering the tube-press, which created a pressure of 14,000 lb. to 28,000 lb. per square inch, was treated in a set of crushing rolls, a rotary drier, sieve, auxiliary crushing-rolls, and cooling-plates with scrapers. The equipment also comprised a small hydraulic hand-press for making preliminary experiments.

The experiments were divided into three periods. From 1904 to 1907 the work was carried on at St. Louis, and the Johnson, American Compressed Fuel Company, and Renfrow machines were used. From 1907 to 1910 at Norfolk, the Johnson and Renfrow (improved) plants were employed, together with a German Schlickeysen peat-machine. And at Pittsburg, from 1910 onwards, the experiments were confined to the German lignite plant and to the small hand-press, although the English machine has been placed on its foundation.

The physical tests to which the briquettes were subjected were called the "drop" and the "tumbler," the absorption, density, weathering and compression tests. In the first, the briquettes were dropped on the floor, and the pieces, which were held by a screen with 1 in. square holes, were dropped again. This procedure was repeated five times, and the weight of the pieces, which, after the fifth drop, would not pass through the screen, was determined. In the tumbler test a weighed quantity of the briquettes (about 50 lb.) was rotated for two minutes at 28 revolutions per minute in a sheet-steel cylinder. The parts which were held by a 1-in. screen and a 10-mesh sieve were then weighed. The absorptive qualities of the briquette were tested by weighing, and the rate of absorption each day, and the time required for the absorption to become complete, or for the briquette to disintegrate, were determined. The density was taken by means of a Nicholson hydrometer, and the weather-resisting qualities were assessed by observations extending sometimes for as long as 286 days. For measuring the crushing strength a 200,000 lb. Olsen testing-machine was employed, although it is stated that the amount of handling which the briquettes will stand is given more accurately by the tumbler and drop tests.

The chemical tests included analyses and moisture tests, and extraction tests, using carbon bisulphide as a reagent, were made to determine the percentage of bitumen in the raw and the briquetted fuel. To determine the evaporative and burning qualities, the briquettes were burned under a stationary boiler. Special tests were also made on locomotives and on a torpedo-boat, and in domestic furnaces and foundry cupolas. The locomotive tests show that the evaporative efficiency of briquetted as compared with raw fuel is greater; that firing is easier; and that both the clinker and smoke produced are less. On the torpedo-boat it was found that there was no gain in smoke production, or in efficiency, but that the work of the stokers was lightened, and the boiler capacity increased. The domestic furnace tests proved that, for the low temperatures common in house-heating boilers, pitch is an unsuitable binder, as it volatilised and escaped unburned, or became deposited as tar. It also gave rise to too much smoke.

In the experiments the question of what binder can be used has naturally been investigated in great detail. The coal-tar pitch binders at present employed give briquettes which are water-proof, do not crumble during transport, leave little ash, and can be manufactured at a reasonable cost. Other

binders, notably cereals and "sulphite pitch" (selpech) have an advantage over pitch, inasmuch as they are smokeless in burning, but they are unfortunately not water-proof, so that the briquettes crumble after exposure to the weather. Such briquettes can easily be rendered water-proof, but the cost has hitherto been considered prohibitive. The American experimenters, however, state that their investigations on this head show that the discovery of a cheap water-proofing process is not an impossible achievement. And the patentee of Middleton's starch binder declares that he has already solved the problem, using 2 per cent. of cereal and ½ per cent. of tar, against, in the ordinary process, 8 per cent. of pitch. The cost of manufacture, he claims, is cheaper than in the pitch process so long as the price of pitch is above 42s. 6d. per ton. He states that the fuel, after exposure to the weather for several weeks, shows practically no deterioration.

In addition to detailed experiments with various kinds and percentages of pitch, the bulletin reports the testing of a large number of other binders. These include creosote, asphalt, petroleum (both of paraffin and asphalt bases), lime, clay, wax tailings, and sludge; various wood products, such as resin, tars, wood pulps, and sulphite liquor; various sugar-factory residues, such as beet pulp, lime cake, and the different molasses; starches, slaughter-house refuse, and petroleum products.

In the tests of pitches it was found that the pitch obtained from the distillation of petroleum gas-tar gave the best results, although other pitches distilled from by-product coke-oven tar, illuminating-gas tar, and producer-gas tar proved quite satisfactory. Water-gas pitch, another binder tested, has an advantage over ordinary coal-tar pitch in that the proportion of free carbon present is only 10 per cent., as against as much as 30 to 40 per cent. with the ordinary material. The free carbon is useless as a binder, and acts merely as a diluent of the bituminous matter. In all pitches it is important to select a material that is not too hard. The actual hardness required varies with the time of year and the climate; but, generally speaking, it was found that pitch which becomes brittle when dropped into water at 55 deg. Fahr. is of the correct texture. The harder pitches have been robbed of the creosote and lighter oils during distillation, so that pitches from which these oils have been distilled off should be avoided. It is also better for briquetting purposes that the pitch should be prepared in this way rather than by distilling all the oil, and then reducing the pitch with the naphthaline and creosote oils, as is sometimes done. As an example of the disadvantage of using the harder pitches, it may be said that in one experiment with a pitch of this kind, 13 to 18 per cent. was found necessary to make good briquettes, while, when a pitch with the proper amount of light oils was tried, 6 to 9 per cent. proved sufficient. Other experiments show that from 7½ to 14 per cent. of volatile oils is the correct proportion to give the proper binding qualities, and that from 6 to 9 per cent. of pitch of this kind will make good briquettes from most bituminous and anthracite coals. To mix with a non-coking coal 10 to 20 per cent. of a coking coal is better than increasing the percentage of pitch.

Of the other binders tried it was found that clay, lime, cement, magnesium oxide, plaster-of-paris, acid sludge, sugar-factory residues, slaughter-house refuse, and wood products are all unsatisfactory, although some of the last-named give good results in combination with other binders, and seem for that reason to deserve further investigation. Wax-tailings give fair results, but are not considered altogether satisfactory, while crude petroleum, although answering well, is deemed unsuitable for working on a commercial scale. Resin, used in conjunction with pitch or petroleum, and a percentage of lime to prevent smoking, makes a good binder; but here, again, the cost makes commercial application impossible. Asphalts are also rather too expensive in most places, and give only fair briquettes, but asphaltic tar was found useful as a water-proofing material in briquettes made with starch.

In fact, the only really good binders besides pitch were found to be starch or flour, and sulphite pitch. None of these is water-proof, but a careful study was made of water-proofing processes, and, as stated above, it is believed that a successful and inexpensive process can be discovered. When using corn starch only 2 to 4 per cent. is required with ordinary coals. The briquettes made with this binder were found to be smokeless. They held their shape well in the fire until completely consumed, and, although the heat value of the binder is small, it leaves no ash. Messrs. Yeadon, Son and Co., of Leeds, are, we understand, constructing a plant for Russia to briquette lignite, with a binder made of finely-ground meal and mazut, and a small proportion of pitch.

Sulphite pitch, also known as cell pitch, is made from the waste liquors which are produced in the sulphite process of manufacturing paper pulp from wood. Until recently these liquors had no commercial value, and their proper disposal was a serious matter, since, if discharged into rivers, they polluted the water and killed such fish as were contained in it. In making the pitch, the liquor is concentrated to a syrup in a sextuple-effect evaporator, and solidified into pitch as a thin film on two rotating steam-heated drums. With some coals, less than half the quantity of cell pitch is required as compared with ordinary pitch; but with others, in the American experiments, the percentage necessary was the same for each material. German experiments, on the other hand, incline to the smaller value. Briquettes made with this binder are smokeless and odourless, and the price of the material, if there are cellulose mills at hand, is low. In the Pollacsek process, used by the Hungarian Government for its collieries, sulphite liquor is employed, and from 3 to 5 per cent. is found to give good briquettes. The briquettes made with sulphite pitch can be rendered water-proof by drying at a temperature of 300 deg. Cent., or by the addition of certain chemicals, the nature of which at present is not divulged. With the latter process, the cost of water-proofing is estimated at 1s. 6d. per ton of briquettes. It is thought at present that the sulphite process will be more useful for anthracite than for bituminous coals, but that it also will be widely employed in preference to pitch in briquetting ores for smelting.

The cost of manufacturing briquettes in England, exclusive of materials, is estimated at about 1s. 6d. per ton of briquettes, and, using 8 per cent. of pitch, the cost of the binder will be about 3s. per ton of briquettes. The cost of the binder, using 2 per cent. of cereal and ½ per cent. of tar, will be about the same, on Middleton's process, when the cereal costs 7*l.* 10s. per ton. In Germany the cost of making lignite briquettes, including all materials, works out at 7s. 6d. per ton, the lignite being taken at ½d. per bushel.

There is evidently a large field for the development of this industry, and the briquetting of ores for smelting, which has not been investigated in the American experiments, is likely to be even more important than the briquetting of coals. Not only iron, but copper, nickel, and other ores can be made into briquettes with advantage.

THE TURKISH NAVAL CONSTRUCTION WORKS.

In December last the Ottoman Government granted a concession to the two great naval construction firms, Messrs. Vickers, Limited, and Sir W. G. Armstrong, Whitworth and Co., Limited, for the re-organisation and complete control of the docks and arsenals at Constantinople, to fit them immediately for the repair and refit of naval and mercantile ships, and, as soon as possible, for the building of all types of vessels. All the preliminary work has been completed, practical operations have commenced, and it is therefore possible to give some idea of the scope of the work. The new company have taken over the dry docks at Constantinople, with the existing workshops there, and the arsenal at the Golden Horn. At the former, which has a very extensive water frontage, there are three graving-docks, one of them 513 ft. long and 62 ft. wide, with a depth of water on the sill of 29 ft., while the corresponding dimensions of another are 400 ft., 72 ft., and 35 ft. It will be obvious that these were not sufficiently large to take the present-day battleship, and the concessionaires have lost no time in ordering a floating dock, which is to have a lifting capacity of 33,000 tons. This will be moored at a new establishment on virgin soil on the southern shore of the Gulf of Ismid, some 50 miles from Constantinople. Here large workshops are to be erected to undertake repair work on the ships while in dock. It is contemplated that the iron-workers' shed, for instance, will be 250 ft. by 150 ft., the engineers' shop 250 ft. by 100 ft., and the woodworkers' shop 150 ft. by 100 ft.; but in all cases these buildings will be so arranged that they can be extended, while provision is made for shipbuilding berths. A wharf for the importation of material is being constructed. A new town is arising, and it is worth noting that the rent is to be from a sixth to an eighth of the wages paid. Indeed Ismid promises ultimately to be a very important naval base, the anchorage being specially satisfactory.

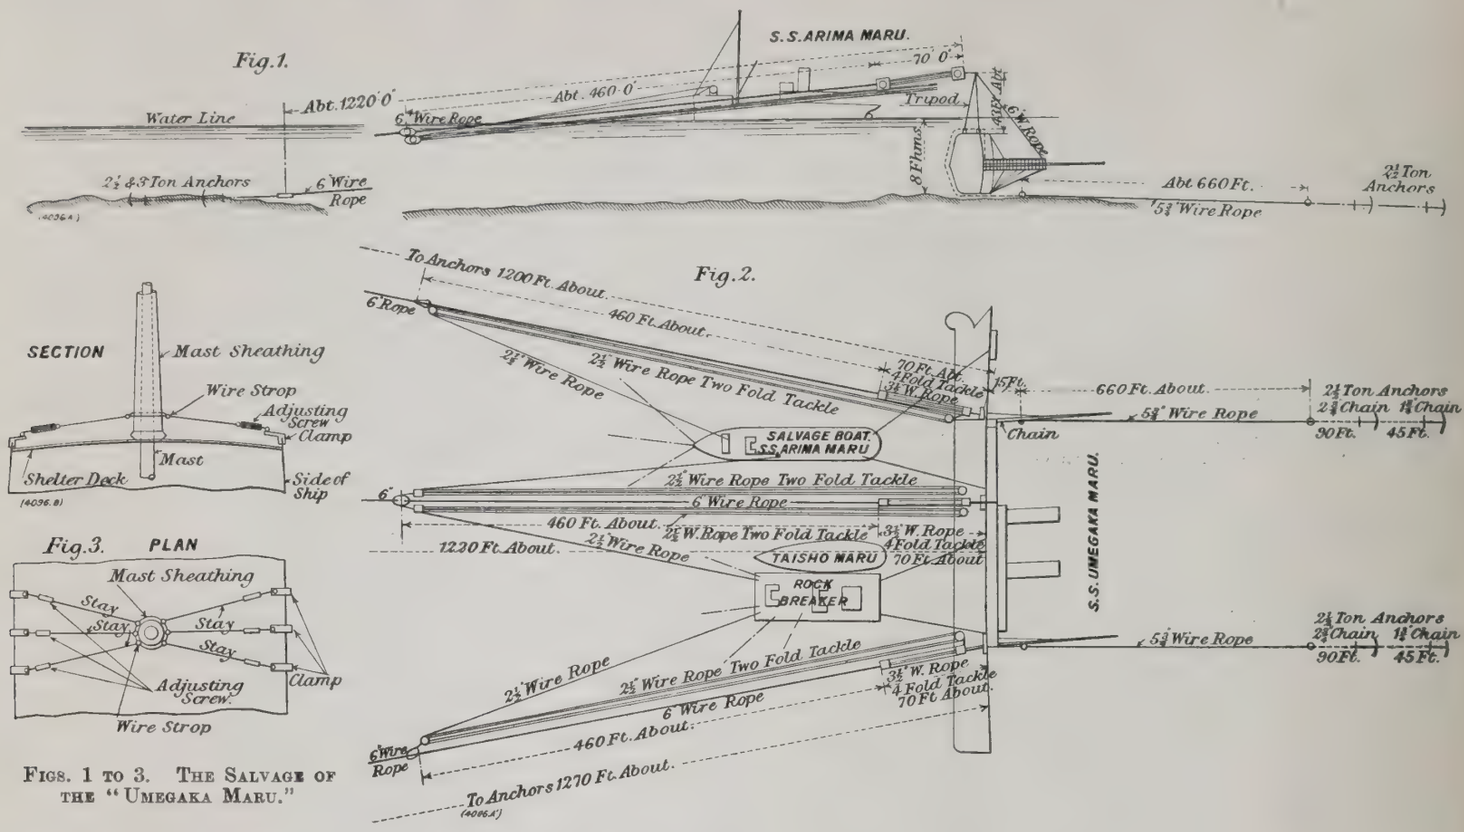
Repair work is in progress already at the existing works, the graving-docks being adequate for the great majority of merchant vessels frequenting Constantinople and trading through the Bosphorus, and as no adequate repairing facilities exist in this region of the Mediterranean, the advent of the Armstrong and Vickers firms is welcomed by the mercantile marine interests. The buildings, both at the docks and arsenal, are substantial masonry structures, but the roofs require extensive repair. The machinery equipment is moderately good, but not powerful or efficient enough to deal with the overhaul of modern turbine and gun-mounting machinery. There is, therefore, in progress a rearrangement of the departments and a large amount of new machinery is being ordered. All such machinery is to be exempt from customs duties. There are three building-berths at the works, but the declivity is too great, so that they will be reconstructed and lengthened.

The intention as regards new construction is to hasten slowly: destroyers will first be undertaken, then scouts, and probably in two years or so second-class cruisers, followed by battleships of all classes. Similarly, the Ottoman Government, while eager to organise a *personnel* of Turkish officers, have placed few restrictions on the English companies, being content to repose full confidence in them. Thus the majority on the Board of Directors will always be British, for the first five years the chairman will be English, for the second ten years Turkish, and thereafter an English and Turkish director will preside for one year alternately. Two Commissioners are to represent the Ottoman Government, but they have no vote; their's is a watching brief, for it will be understood that all work done for the Ottoman Government is to be paid for on the time and material principle, plus establishment charges and a fixed profit of reasonable amount from the point of view of both parties. Of course, as many native workers as possible will be employed, but there are no stipulated limits, as is often the case under analogous contracts. The staff is almost entirely British. Apprentices are to be trained and evening classes instituted, and at the end of ten years 50 per cent. of the entire staff are to be Ottoman subjects. The hours worked are to be nine and a-half per day, and the wages of Ottoman workmen range from 2s. 2d. per day for labourers to 4s. 6d. for platers and blacksmiths, the great majority getting about 3s. 8d. per day. The concession is for a period of thirty years, and during that period no other works, company, or private party, whether Ottoman or foreign, will be granted any concession or authorisation for the working of docks or naval or military construction works in Turkey. The important outstanding feature is the will of the Ottoman Government to encourage British enterprise, to ensure a fuller influence for Britain in the Near East, and closer association with British shipping and industry.

JAPANESE INSTITUTION OF NAVAL ARCHITECTS.

On June 6 and 7 last the Japanese Institution of Naval Architects held a meeting at Tokyo under the presidency of Vice-Admiral M. Kondo, one of its Vice-Presidents. On this occasion, in addition to papers being read, visits were made to some works of interest in Tokyo and to the Taisho Exhibition, now being held there. There was also a social gathering at the close of the meetings. The principal papers read were as follow:—"The Salvage of the Umegaka Maru," by Mr. M. Haramiishi, Engineer to the Mitsu Bishi Dockyard and Engineering Works, Kobe; "A Self-Recording Strain-Meter," by Professor S. Terano, and Assistant Professor T. Yamamoto, both of the Tokyo Imperial University; "Ramsbottom's Packing-Rings," by Mr. Kenji Nakagawa, Engineer to the Mercantile Marine Bureau, Department of Communications;

"Standardisation of Experimental Data of Engine Fuels," by Engineer-Captain Miyagawa, I.J.N.; and "Safety at Sea," by Professor F. P. Purvis, Tokyo Imperial University. The last of the papers just mentioned we print in full on page 140 of the present issue; of three others we now propose to give summaries.



FIGS. 1 TO 3. THE SALVAGE OF THE "UMEGAKA MARU."

THE SALVAGE OF THE "UMEGAKA MARU."

This ship belonged to the Japanese Volunteer Fleet, and was sunk in September, 1912, in the Straits of Moji. The paper acknowledges the assistance rendered in the raising of the ship by Mr. A. P. Macfarlan, special officer of the Salvage Association, London, and describes the work of salvage as carried out by the author's company. The ship lay on her port side on hard sand, in 6 to 9 fathoms at mean tide, the starboard side forward being just awash at ebb tide. The strength of current in these straits is given on the chart as 2½ knots, but is probably more. Salvage work was commenced in November, 1912.

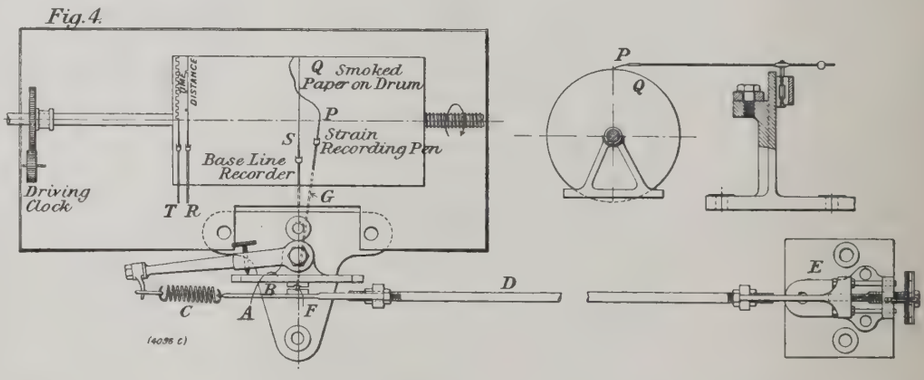
In order to get the ship on a level keel the rooms between the shelter-deck and boat-deck were first made water-tight in seven sections, and buoyancy obtained at this part of the ship by pumping them clear of water. Three tripods, each 40 ft. high, were next erected on the starboard side of the hull and were suitably stayed by guys, the arrangement of these being shown by Figs. 1, 2, and 3, annexed. To the tops of the tripods tackles were connected capable of exerting a pull of 50 tons at the top of each tripod, the tackles being attached to three 6-in. wire cables, which were led off a considerable distance and connected to three groups of anchors suitably disposed. The centre group consisted of two 3-ton and two 2½-ton anchors, while the outer groups each consisted of two 3-ton and one 2½-ton anchors.

The falls from the tackles were led to the salvage steamer Arima Maru, and to a large rock-breaker, which were equipped with the necessary hauling plant, and these vessels again were connected to the Umegaka Maru. The positions occupied by the Arima Maru and the rock-breaker, together with the arrangement of the moorings and the tackle generally, are clearly shown by the plan, Fig. 2.

To assist the righting forces thus applied two 200-ton hydraulic jacks were placed between the ground and the port sheer-strake, and, in addition, weight in the form of sand-bags was applied to the starboard side. After due adjustments, the first operation was successfully carried out, and the ship brought to a level keel on March 19, 1913.

The tripods, platform, and other parts not required were then removed, and a cofferdam, 242 ft. in length, was constructed and made water-tight. Precautions were taken to prevent the bow from rising prematurely. The pumps, &c., were adjusted until they consisted of the following:—Ten centrifugals, 8 in. to 12 in.; two specials, 18 in.; two pulsometers, 10 in. Using these appliances the final operations were commenced on May 15, 1913.

By judiciously drawing from the different connections through the various pumps and pulsometers the ship was brought bodily to the surface on a practically level keel. There was a danger at one time of the current taking charge; the anchors holding the stern dragged, and the ship swung from her position, but was checked before any damage was done. As the amount of water aboard was reduced, a list of 12 deg. to port was experienced. The cofferdam and other temporary structures were then removed, the list thereby lessened, and the pumping continued until, on May 18, the maximum draught was brought to 24 ft.; the ship was then towed to a safe mooring in Moji Harbour, and, after small repairs, was finally towed by easy stages to Kobe.



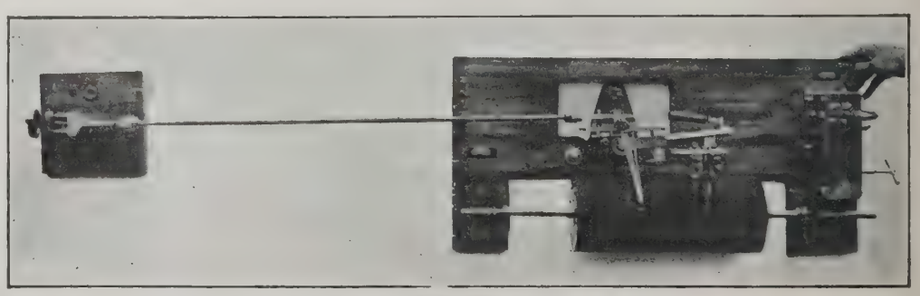


FIG. 5.

FIGS. 4 AND 5. A SELF-RECORDING STRAIN-METER.

A SELF-RECORDING STRAIN-METER.

The instrument described in the paper by Professor S. Terano and Assistant Professor T. Yamamoto is an outcome of Mr. Stromeyer's well-known arrangement made self-recording, and applicable to launching observations in the first

instance, but also ultimately to the recording of stresses at sea. The authors hold that while Mr. Stromeyer's idea was an indicator almost weightless and inertialess, they had found that at the time of the launch of a ship changes of strain were so slow and gradual that practically no shocks have to be provided for; they are therefore justified in making the indicator a little heavier and stiffer. A general diagram showing the arrangement of the instrument is given in Fig. 4, and a photographic view in Fig. 5, page 128. From these views it will be seen that there are two sliding blocks A and B; A is fixed to the stand of the instrument, and through it to the ship's structure, and B is held against A by a small spiral spring C set in balance with the long tube D; the other end of D is connected to the micrometer E, which is also attached to the ship's structure. Small triangular grooves are cut in the faces of A and B, and a knife-edged hard-steel pin F is inserted between them; an aluminium needle G, attached to the pin F, and carrying a light pen P at its end, registers on the drum Q, covered with smoked paper, the relative movement of the blocks. Another pen S, fixed to the stand, traces a base line. The

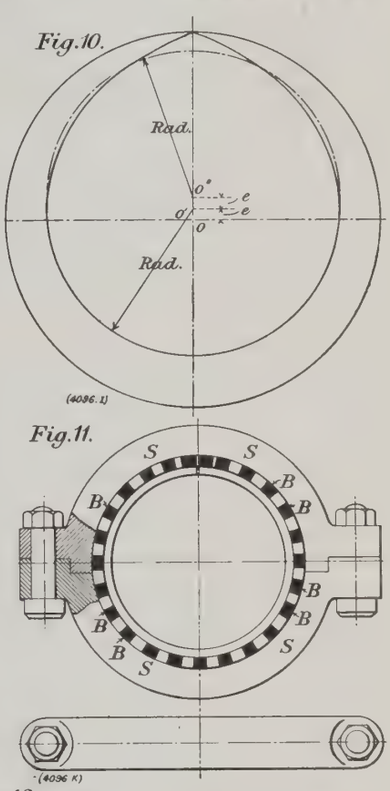

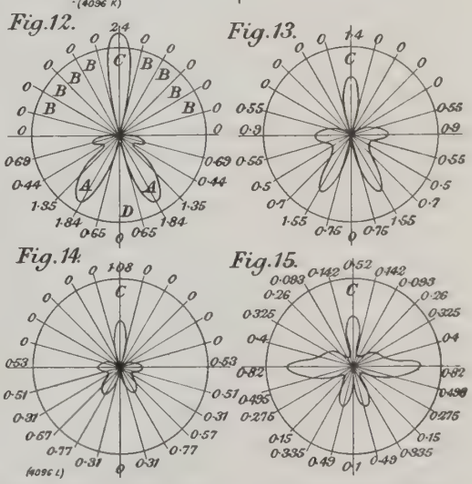

FIGS. 10 TO 15. EXPERIMENTS ON RAMSBOTTOM PISTON-RINGS.

relative movements of A and B (due, for instance, to strain in the ship's structure between F and E) are thus magnified and recorded; the micrometer E allows a scale to be made for accurate calibration. For use in connection with launching observations, two more pens, T and R, give time and the distance run by ship.

Three of these instruments have now been made. They have been used at the launch of the Anyo Maru, Sakaki Maru, H.J.M.S. Kirishima, and H.J.M S. Haruna, with results shown in Figs. 6 to 9, page 110. In the Anyo Maru (460 ft. by 60 ft. by 32 ft. 6 in.) the instrument was placed on the upper deck, with length F E = 5 ft. A maximum compressive stress of 1.57 tons per sq. in. (taking E = 13,400 tons) was recorded at a position a little after that of lift at stern, by calculation (Fig. 7). A Stromeyer's indicator alongside showed 1.47 tons per sq. in. In the Sakaki Maru, of the Volunteer Fleet (358 ft. by 46 ft. by 26 ft.), the instrument was placed on the bridge-house; the record (Fig. 8) shows 0.5 ton per sq. in. compression at 70 ft. run, 0.4 ton tension at 200 ft., and maximum compression 1.3 tons at a position 30 ft. after lift at stern, as calculated. In the cruiser Kirishima (27,500 tons) two instruments were used, one placed on the flying-deck, the other on the tank top. Some peculiarities in the record of the latter seem due to local strains, and some failure to give a proper record affects the maximum reading of the former; but maximum compression of the latter is well shown (2.75 tons), and the sudden change from tension to compression, and *vice versâ*, just as the ship left the ways is recorded as simultaneous (Fig. 9). Her sister-ship Haruna gives a more satisfactory result, with maximum tension 3.8 tons. The vertical vibrations (about 60 per minute), occurring immediately after the ship left the ways, are well represented by the variations in the recorded strains (Fig. 6).

Ramsbottom Packing-Rings.

In this paper the author describes experimental investigations into the distribution of pressure round the ring; (α) when the inner circle is concentric with the outer; (β) when it is eccentric; and (1) when the rings are turned once only; (2) when they are tightened after the first turning with a strong belt and returned. In addition he suggests a modified design of ring, with the inner surface formed of two half-circles differing slightly in their eccentricity from one another, as well as from the outer surface. Fig. 10, page 129, shows this design (upper part the chain line) in comparison with Unwin's theoretical curve.* Mr. Nakagawa's experiments were made as follow:—His apparatus consisted of two cast-iron straps S S, Fig. 11, having inside diameter 6½ in., turned to a true circle; another ring, having 6½ in. outside and 6 in. inside diameter, was cut into a number of separate pieces or blocks B B B. The Ramsbottom ring to be experimented on was inserted inside the blocks B B B and the strap S S screwed up, the condition thus approximating to a ring inside a cylinder 6 in. in diameter. The force needed to move each of the blocks B B B was then ascertained by a simple mechanism (lever and weight); as no lubricant was used, this frictional force was taken as a measure of the pressure exerted at the several blocks. The Ramsbottom rings upon which Mr. Nakagawa experimented had all a depth of ¼ in., and a mean thickness of $\frac{3}{16}$ in.; excess of outside diameter of ring over cylinder diameter, ⅛ in. Several diagrams are given, and of these, four only are reproduced on page 129, viz.:—Fig. 12—Ring with inner and outer circle concentric, once turned; Fig. 13—Circles $\frac{1}{32}$ in. eccentric, once turned; Fig. 14—Circles concentric, double turned; Fig. 15—Ring with two half inner circles, one $\frac{3}{64}$ in., the other $\frac{3}{32}$ in. eccentric from the outer.

The radii vectors of the curves drawn on these diagrams represent the pressures in the various cases. Uniformity of pressure is obviously the ideal condition to be aimed at; zero values at one part of the circumference mean enhanced values at others, and the author points out that in Fig. 15 there is no zero value.

THE REACTION OF A STEAM-JET.

When a jet of steam issuing from a nozzle is delivered in a fully-expanded condition, there is no difficulty whatever in deducing the reaction of the jet from theoretical principles. In such case, the final velocity of flow and the weight delivered per second can both be easily calculated, and the reaction is then given by the expression:—

$$R = \frac{w\,v}{g}$$

where R denotes the reaction in pounds per square inch, v the final velocity of the steam in feet per second, w the weight delivered in pounds per second, and g the acceleration of gravity.

In fact, if x be the ratio of the initial pressure to the final, P the initial absolute pressure in pounds per square inch, and γ the index in the usual equation for the adiabatic expansion of steam —viz., $P\,V^{\gamma} = \text{constant}$, we have—

$$R = \frac{2\gamma}{\gamma - 1} \cdot P\left(\left(\frac{1}{x} \right)^{\frac{1}{\gamma}} - \frac{1}{x} \right) a,$$

which if γ be taken at $\frac{10}{9}$ reduces to

$$R = 20\,P\left(\left(\frac{1}{x} \right)^{\frac{9}{10}} - \frac{1}{x} \right) a \quad . \quad . \quad . \quad (1)$$

where a denotes the area of the jet in square inches.

So long as x does not exceed a certain limiting value (approximately 1.73 in the case of steam) this equation gives accurately the theoretical reaction of the jet, the actual figure found in practice being, of course, always a little less owing to the loss of velocity which results from nozzle friction. It has, however, long been known that if the value of x exceeds the limit stated the steam, as delivered from a convergent nozzle, may be very far from fully expanded, and the calculation of the reaction to be expected in such case then becomes somewhat more complicated, but, as we shall show, can nevertheless be deduced fairly simply. The matter is of some importance, since in not a few nozzle experiments, of which data have been published, the steam has completed its expansion after it has cleared the nozzle. The velocity of efflux cannot then be deduced directly from the observed reaction, which, in fact, gives the final velocity of the fluid, and not its velocity at the plane of discharge. Obviously, the expansion which occurs after the jet has cleared the nozzle will take place in all directions, and contribute much less to the axial velocity of the jet than the amount properly due.

The losses thus occurring do not seem fairly attributable to the nozzle, but rather to the misuse of it in improper conditions. Some few experimenters have attempted to correct their results accordingly, but in such cases as have come under our notice have done so incorrectly. Confining our attention to the case of a convergent nozzle, the reaction theoretically due in the case where the final pressure of the steam is less than 0.58 P is given by the relation:—

$$R = \overline{R} + (0.58\,P - p)\,a,$$

where $\overline{R}$ denotes the value of R when p (the external pressure) is equal to 0.58 P.

Taking γ as $\frac{10}{9}$ this "critical" reaction has the value:—

$$\overline{R} = 0.65\,P\,a.$$

So that—

$$R = (1.23\,P - p)\,a \quad . \quad . \quad . \quad (2)$$

Suppose, for example, that P be 200 lb. absolute and p be 14.7 lb. absolute, whilst $a = 1$ sq. in. Then the reaction from a jet flowing under this pressure-difference from a convergent nozzle would by equation (2) be 232.7 lb. On the other hand, were the jet fully expanded on delivery, as it might be in a frictionless divergent nozzle, the reaction would be 272 lb.

The rule given as equation (2) can be proved by the following considerations. Let there be a cylindrical nozzle-box of cross-section A, having formed in its front cover a converging nozzle of which the outlet has the area a. Let P be the pressure inside the box, and p the external pressure. At the outset let p be equal to P, and afterwards gradually reduced. As the external pressure is diminished, "news" of the change in the external status is transmitted back along the jet to the interior of the box, where the conditions adjust themselves accordingly. At the outset each reduction in the external pressure is followed by an increase in the velocity of efflux, which finally attains the velocity of sound when the external pressure is 0.58 of the internal. The speed with which "news" of a change in the external conditions is transmitted back along the jet is, however, also the speed of sound; hence once the velocity of efflux attains this limit the steam in the interior of the box can never get to "know" of any further diminution in the external conditions, and any such further diminution can therefore in no way affect the condition of things inside the nozzle-box.

Now the back thrust on this nozzle-box arises in part from the internal pressure and in part from the external. On the back cover there is a pressure equal to P A. On the front cover the area exposed to pressure is A − a; but over this area the pressure is not uniform, since it is disturbed by the flow of the fluid to the nozzle, part of the pressure which in the static condition would come on this cover being, in fact, balanced by the curvature of the stream-lines. Hence the average pressure on the area A − a is not P, but some smaller pressure $\overline{P}$. Thus the contribution to the total reaction made by the internal pressures is $P\,A - \overline{P}\,(A - a)$.

At the same time the external pressure contributes the amount $-\,p\,a$, where p denotes this external pressure.
